ABSTRACT

The Effects of Mergers: An International Comparison

by Klaus Gugler, Dennis C. Mueller, B. Burcin Yurtoglu, and Christine Zulehner*

This paper analyzes the effects of mergers around the world over the past 15 years. We utilize a large panel of data on mergers to test several hypotheses about mergers. The effects of the mergers are examined by comparing the performance of the merging firms with control groups of nonmerging firms. The comparisons are made on profitability and sales. The results show that mergers on average do result in significant increases in profits, but reduce the sales of the merging firms. Interestingly, these post merger patterns look similar across countries. We also did not find dramatic differences between mergers in the manufacturing and the service sectors, and between domestic and cross-border mergers. Conglomerate mergers decrease sales more than horizontal mergers. By separating mergers into those that increase profits and those that reduce them and by then examining the patterns of sales changes following the mergers, we determine the effects of mergers on efficiency and market power. Our results suggest that those mergers that decrease profits and efficiency account for a large proportion. However, we can also identify mergers that increase profits by either increasing market power or by increasing efficiency. The first conclusion seems to be a more likely explanation for large companies, whereas the latter is likely to be true for small firms.

Keywords: Mergers, Acquisitions, International Comparison

* This paper was presented at the Corporate Governance conference organized by the DIW, Berlin, November, 2000; at the 9th Annual WZB/CEPR conference on Industrial Organization, Berlin, December 2000; and at the "Ausschuß für Industrieökonomik" of the Verein für Socialpolitik, Passau, March 2001. We thank all the participants for the useful discussions and in particular A. D. Cosh, M. Erlei, O. Fabel, P. A. Geroski, P. Guest, A. Hughes, D. Marin, H. Odagiri, A. Singh and K. Stahl. We also thank J. Jung for excellent research assistance. Financial support of the "Jubiläumsfonds der Oesterreichischen Nationalbank", project 8861, is gratefully acknowledged.

ZUSAMMENFASSUNG

Die Effekte von Fusionen: Ein internationaler Vergleich

Dieser Artikel analysiert die Effekte von Fusionen, die weltweit über die letzten 15 Jahre stattgefunden haben. Wir vergleichen die Gewinn- und Umsatzentwicklung von fusionierenden Firmen mit der Entwicklung von nicht-fusionierenden Firmen. Die Resultate zeigen, dass Fusionen im Durchschnitt zu signifikant höheren Profiten führen, aber dass die Umsätze im Vergleich zur Kontrollgruppe zurückbleiben. Interessanterweise sind diese Effekte bei Vergleichen zwischen den verschiedenen Ländern, bei einem Vergleich zwischen Industriesektor und Dienstleistungssektor bzw. zwischen nationalen und grenzüberschreitenden Fusionen ziemlich ähnlich. Konglomerate Fusionen reduzieren die Umsätze mehr als horizontale Fusionen. Um die Effekte der Fusionen auf die Marktmacht bzw. die Effizienz zu analysieren, teilen wir zuerst die Fusionen in gewinnsteigernde und gewinnreduzierende Fusionen, um dann die Umsatzentwicklung zu betrachten. Unsere Resultate zeigen, dass ein großer Prozentsatz der Fusionen die Gewinne und die Effizienz reduzieren. Wir können jedoch auch Fusionen identifizieren, die die Gewinne entweder durch Marktmacht- oder Effizienzsteigerungen erhöhen. Die erste Erklärung ist wahrscheinlicher für große Firmen, die zweite für kleine Firmen.

The past century saw five great merger waves – one at its beginning, and successive waves at the ends of the ‘20s, ‘60s, ‘80s and ‘90s. While much of the earlier merger activity was confined to North America and Great Britain, the most recent wave has engulfed all of the major industrial countries of the world. And, as befits a global economy, it has been composed of an increasing percentage of cross-border acquisitions. What have been the causes of these great bursts of merger activity? What have been their effects? In this paper we focus largely on the second question, but the answers that we give to it will also shed light on the first. We confine our analysis to mergers taking place in the last two decades, but include in it mergers from around the world including also cross-border acquisitions.

The hypotheses as to why mergers¹ occur can be grouped into three broad categories. Of these, the first two presume that the managers of the merging companies seek to maximize profits or shareholder wealth. Under this assumption any merger must be expected to either increase the market power of the merging companies or reduce their costs. The third set of hypotheses includes those that posit other managerial goals than profits, as say the growth of the firm, or quasi-irrational behavior as might occur because managers are overcome by hubris.

From the point of view of the theory of the firm, it is important to determine whether mergers are best explained by one of the hypotheses from the third category, or by a hypothesis that presumes profits maximization. If *all* mergers are consistent with profits maximization, then corporate governance structures can be assumed to be designed in such a way as to align shareholder and managerial interests. If, on the other hand, a large fraction does not appear to increase shareholder wealth, corporate governance structures must be assumed to be deficient in bringing about such an alignment. We attempt to determine whether mergers increase market power or efficiency by examining their impacts on company sales and profits. In this way, we seek to determine to what extent mergers fall into each of these three categories.

The paper proceeds as follows. In the following section we describe the methodology used to determine the effects of mergers. Our data base is described in section II. Sections III and IV present our overall findings and those that are specific to the question of whether mergers increase efficiency or market power. In section V we compare our findings with those previously reported in the literature. The

sample is divided according to the mergers' effects on market power and efficiency in section VI. Conclusions are drawn in the final section.

I. Methodology

A. A Categorization of the Effects of Mergers

It is reasonable to assume that all firms possess *some* market power. Even a company selling what appears to be a homogeneous product generally has some power to set price due to locational advantages, a reputation for reliability or good service, and so on. Thus, we shall assume that all firms face negative sloped demand schedules. The first-order condition for profits maximization then implies that firm *i* chooses a price p_i that satisfies the following condition

$$\frac{p_i - c_i}{p_i} = \frac{1}{\eta_i} \tag{1}$$

where c_i is the firm's marginal costs and η_i is its elasticity of demand. Equation (1) is of course the familiar Lerner condition for profits maximization for a monopoly except that the firm's demand elasticity replaces the industry elasticity. The firm's demand elasticity takes into account the conjectured responses of its rivals to any change in price it might make.

A merger, which increases the market power of a firm, must do so by either increasing the degree of collusion among the firms in the industry or by increasing its market share. Either way the *firm's* demand elasticity, η_i , falls and it raises its price. If $c_i > 0$, (1) implies that $\eta_i > 1$, and thus that *i's* sales fall when it raises its price. We thus predict for mergers that increase market power increases in profits and declines in sales (see cell 2 in Table 1).

Table 1: Possible Consequences of Mergers

	$\Delta\Pi > 0$	$\Delta\Pi < 0$
$\Delta S > 0$	1 Efficiency Increase	3 Market Power Reduction (?)
$\Delta S < 0$	2 Market Power Increase	4 Efficiency Decline

A merger, which increases efficiency leaves η_i , unchanged, but lowers c_i . The profits maximizing price falls and sales expand. We thus predict for mergers that increase efficiency increases in both profits and sales (cell 1 in Table 1).

Although these strike us as the most plausible predictions to make about market power and efficiency enhancing mergers, the variety of assumptions that one can make about the characteristics of cost functions and oligopolistic interactions is so large that it is probably possible to construct an example in which any one of the four possible combinations of profits and sales changes in Table 1 follows a merger that increases either efficiency or market power. For example, with an initial situation in which n firms are in a symmetric Cournot equilibrium, if marginal costs are sufficiently low so that the equilibrium is in the inelastic portion of the demand schedule, a merger which both reduced the number of firms *and* led to perfect collusion among them *might* increase both the profits and the sales of the merging firms.²

A more plausible possibility would be a merger, which increased efficiency by reducing fixed costs, but left marginal costs unchanged. Profits would then rise, but sales would remain unchanged. Of course, in the long run all costs are variable, and thus we would expect that a merger that reduced fixed costs would eventually lead to lower prices and increased sales. But we shall only measure the effects of mergers for up to five years after they occur, and five years are arguably too short of a time interval to see increases in sales for a merger that reduces fixed costs. Thus, it is possible that a merger, which only reduced fixed costs, would increase profits without increasing sales.

Mergers that reduce efficiency should reduce *both* profits and sales (cell 4). Such mergers might take place either because profit-maximizing managers make mistakes, or because they pursue other goals than profits, like growth.

The most puzzling entry in Table 1 appears in cell 3. Profits decline, but sales increase. Since this outcome is the mirror image of cell 2, we have labelled it “Market Power Reduction,” but the question mark indicates our uncomfortableness with this categorization. No profit-maximizing manager would undertake a merger because she wanted to increase the amount of competition her firm faces. Sales increases coupled with profit declines might be observed, if the managers were sales or growth maximizers. Thus, both cells 3 and 4 could contain mergers motivated by the pursuit of growth.

Nevertheless, both the motivation behind and the consequences of mergers falling into cell 3 are more difficult to identify than for the other three cells.

We think that the categorization of mergers in Table 1 is reasonable and helpful when making normative judgments about the consequences of mergers. But the reader is of course free to make his or her own categorization. Our main goal in this paper is simply to report what the effects of mergers on the profits and sales of the merging firms have been. We turn now to a description of the procedures used to make this determination.

B. Measuring the Effects of Mergers

To measure the effects of mergers on sales and profits properly, we need to control for general changes in the economy that might affect the merging companies' performance. Previous studies have employed industry means, size matched non-merging firms and the median firm from a merging firm's industry.³ We match each merging company to the median firm in its industry, and thus assume that the merging companies' profits and sales would have changed in the same way that the median firm's profits and sales in their respective industries changed.⁴

Consider first the problem of predicting the merging companies sales. Define:

S_{Gt+n} as the sales of the acquiring company in year $t+n$,

S_{Dt} as the sales of the acquired company in year t ,

S_{Ct+n} as the predicted sales of the combined company in year $t+n$,

S_{IGt+n} as the sales of the median firm in the industry of the acquiring company in year $t+n$, and

S_{IDt+n} as the sales of the median firm in the industry of the acquired company in year $t+n$.

The predicted sales for the combined company in year $t+n$ is estimated as follows:

$$S_{Ct+n} = S_{Gt-1} \frac{S_{IGt+n}}{S_{IGt-1}} + S_{Dt} \frac{S_{IDt+n}}{S_{IDt}} \quad (2)$$

The sales of the acquiring company are projected relative to its sales in the year prior to the merger, the sales of the acquired company are projected relative to its sales in the year of the merger.

It often happens, of course, that companies make several acquisitions over short spans of time. To allow for this possibility we amend Eq. 2 to take into account mergers occurring after time t . If, for

example, a firm made one acquisition in t and another in $t+2$, then the amended formula for predicting S_{Ct+n} would look like the following (for $n \geq 2$)

$$S_{Ct+n} = S_{Gt-1} \frac{S_{IG\ t+n}}{S_{IG\ t-1}} + S_{Dt} \frac{S_{ID\ t+n}}{S_{ID\ t}} + S_{Dt+2} \frac{S_{ID\ t+n}}{S_{ID\ t+2}} \quad (3)$$

Many firms both acquire and sell assets. We also need to account for the effects of spin- and sell-offs on the merging companies' sales. We do so by treating these sales symmetrically to acquisitions. Namely, we subtract the sales of any part of a company sold or spun-off during the five years after a merger, again scaling the sales of the spun-off unit by the changes in sales for the median firm in its industry.

If, for example, a firm made one acquisition in year t , another in year $t+2$ and spins or sells off a company in year $t+3$, the final formula for predicting S_{Ct+n} would then be (for $n \geq 3$)

$$S_{Ct+n} = S_{Gt-1} \frac{S_{IG\ t+n}}{S_{IG\ t-1}} + S_{Dt} \frac{S_{ID\ t+n}}{S_{ID\ t}} + S_{Dt+2} \frac{S_{ID\ t+n}}{S_{ID\ t+2}} - S_{St+3} \frac{S_{IS\ t+n}}{S_{IS\ t+3}} \quad (4)$$

where S_{St+3} denotes the sales spun or sold off by the acquiring company in year $t+3$ and $S_{IS\ t+n}$ is the sales of the median firm in the industry of the divested company in year $t+n$.⁵

Our methodology for determining the effects of mergers on sales is to compare the predicted value for the merged company's sales in year $t+n$ after adjusting for all mergers and spin-offs as obtained using Eq. 4, with the actual level of sales of this company.

Projecting the levels of profits is a little more difficult, because they can take on negative and zero values. Taking ratios of profits at different points in time may introduce significant errors. We shall, therefore, use changes in the ratios of profits to total assets to predict changes in the profits of the merging companies. Define:

Π_{Gt+n} as the profits of the acquiring company in year $t+n$,

Π_{Dt} as the profits of the acquired company in year t ,

Π_{Ct+n} as the predicted profits of the combined company in year $t+n$,

Π_{IGt+n} as the profits of the median firm in the industry of the acquiring company in year $t+n$,

Π_{IDt+n} as the profits of the median firm in the industry of the acquired company in year $t+n$.

K_{Gt+n} as the assets of the acquiring company in year $t+n$,

K_{Dt} as the assets of the acquired company in year t ,

K_{IGt+n} as the assets of the median firm in the industry of the acquiring company in year $t+n$, and

K_{IDt+n} as the assets of the median firm in the industry of the acquired company in year $t+n$.

We can now compute the projected change in the returns on the acquirer's assets from year $t-1$ to $t+n$ using again the changes observed for the median (in terms of profitability) company in its industry.

Call this projected change $\Delta_{IG\ t-1,t+n}$.

$$\Delta_{IG\ t-1,t+n} = \frac{\Pi_{IG\ t+n}}{K_{IG\ t+n}} - \frac{\Pi_{IG\ t-1}}{K_{IG\ t-1}} \quad (5)$$

If the median firm in the acquirer's industry earned a .10 return on assets in $t-1$, and a .11 return in $t+n$, then we would predict that the acquiring firm's returns on assets would increase by .01.

Defining $\Delta_{ID\ t,t+n}$ for the acquired firm's industry analogously to $\Delta_{IG\ t-1,t+n}$ gives us the following formula for predicting the profits of the combined company in year $t+n$.

$$\Pi_{Ct+n} = \Pi_{Gt-1} + \frac{K_{IG\ t+n}}{K_{IG\ t-1}} K_{G\ t-1} \Delta_{IG\ t-1,t+n} + \Pi_{Dt} + \frac{K_{ID\ t+n}}{K_{ID\ t}} K_{D\ t} \Delta_{ID\ t,t+n} \quad (6)$$

The profits of the combined company in year $t+n$ are predicted to be the profits of the acquirer in $t-1$, plus the predicted growth in its profits from $t-1$ to $t+n$, plus the profits of the acquired firm in t , plus the predicted growth in its profits from t to $t+n$. Eq. 6 can be modified to take into account additional acquisitions and spin-offs in the same way that Eq. 2 was. Thus, if we take the same example from above where a firm made one acquisition in year t , another in year $t+2$ and spins or splits off a company in year $t+3$, the final formula for predicting Π_{Ct+n} is then (for $n \geq 3$)

$$\begin{aligned} \Pi_{Ct+n} = & \Pi_{Gt-1} + \frac{K_{IG\ t+n}}{K_{IG\ t-1}} K_{G\ t-1} \Delta_{IG\ t-1,t+n} + \Pi_{Dt} + \frac{K_{ID\ t+n}}{K_{ID\ t}} K_{D\ t} \Delta_{ID\ t,t+n} + \\ & + \Pi_{Dt+2} + \frac{K_{ID\ t+n}}{K_{ID\ t+2}} K_{D\ t+2} \Delta_{ID\ t+2,t+n} - \Pi_{St+3} - \frac{K_{IS\ t+n}}{K_{IS\ t+3}} K_{S\ t+3} \Delta_{IS\ t+3,t+n} \end{aligned} \quad (7)$$

where Π_{St+3} are the profits spun or sold off in year $t+3$, $K_{IS\ t+n}$ are the assets of the median firm in the industry of the spun- or sold-off company in year $t+n$, $K_{S\ t+3}$ are the assets of the spun- or sold-off company in year $t+3$, and $\Delta_{IS\ t+3,t+n}$ is the projected change in the returns on the spun- or sold-off company's assets from year $t+3$ to $t+n$.⁶

II. Data Description

Our principal source of data is the *Global Mergers and Acquisitions* database of *Thompson Financial Securities Data (TFSD)*. This company collects merger and spin-off data using a variety of sources such as financial newspapers, Reuters Textline, the Wall Street Journal, Dow Jones etc. The database covers all transactions valued at US \$ 1 million or more. We define a merger as a transaction where more than 50 percent of the equity of a target firm is acquired.⁷ During the period 1981 to 1998, there were 69,605 announcements of such mergers. Our data for the United States begin in the late 1970s, for all other countries in the mid-eighties. Figure 1 presents the total number of deals by completion year.

Figure 1. The Number of Completed Mergers and Divestitures, 1981-1998

Source: SDC Thompson Financial Securities

Panel A of Table 2 summarizes the characteristics of completed mergers. From the nearly 70,000 announced mergers across the world, nearly 45,000 mergers were actually completed with almost half of these taking place in the United States. For the full sample, horizontal mergers make up 42 percent of all mergers, conglomerate mergers 54 percent and vertical mergers only 4 percent. To be defined as a

vertical merger at least 10 percent of the sales (purchases) of the primary 4-digit industry to which one of the merging companies belongs must go to (come from) the industry to which the other belongs. We use the 1992 input-output table for the U.S. economy to make this determination. Horizontal mergers are defined as mergers between two companies with sales in the same primary 4-digit industry. Conglomerate mergers consist of all mergers, which are neither horizontal nor vertical. It is interesting to note that a greater fraction of mergers in the United States appears to be horizontal than for any other area/country category. Despite the step-up in antitrust enforcement under the Clinton Administration, a greater fraction of mergers between 1993 and 1998 was horizontal in nature than from before 1990. In some years the proportion is nearly 50 percent. Roughly one fifth of the mergers are cross-border transactions (22 percent). This number increased from 16 percent before 1990 to 25 percent in the years 1997/1998. In the USA, this percentage rose from just 3 percent before 1990 to 17 percent in the years 1997/1998. Cross-border mergers are particularly important in Western Europe (33 percent) and Japan (53 percent). To arrive at comparable real values, we first convert all variables to USD and deflate by the US-Consumer Price Index with base year 1995. Thus, the average deal value was 220 million 1995-USD.⁸

The samples used for our analysis are much smaller than the numbers in Table 2 suggest due to missing data for relevant variables. Acquiring company balance sheet and market data for the years $t-1$ to $t+5$ relative to the merger year t stem from the *Global Vantage/Compustat* database. Out of the 45,000 completed mergers of Table 2 we could match 17,863 to one of these databases. Some acquiring companies acquire more than one target in a given year, and since our balance sheet information for acquiring companies is on a yearly basis, we aggregate the relevant variables of these targets. This further reduces the merger sample to 14,269 merger years.⁹

On average, acquiring firms are present over a time period of 15 years in our databases. During this period acquiring firms make 2.25 acquisitions and divest 0.83 companies on average. Missing data and the elimination of outliers (we drop the left and right one percent tail of the distribution) reduces the sample to the numbers reported in Table 3.¹⁰ We have attempted to make our samples as large as possible and thus do not limit ourselves to balanced panels, companies making only one merger or the like.

Conglomerate	55.9%	52.6%	54.4%	55.2%	52.6%	54.3%

Notes: The database is the *Global Mergers and Acquisition* database of *Thompson Financial Securities*. It covers all transactions with a value of at least US \$ 1 million. *Continental Europe* includes Austria, Belgium, Germany, Denmark, Spain, Finland, France, Greece, Ireland, Italy, Luxembourg, The Netherlands, Norway, Sweden, Portugal, Switzerland and Island. The *Rest of the World* sample includes more than 100 other countries. *Deal value* is defined as the total consideration paid by the acquirer excluding fees and expenses. The dollar value (deflated by the US-CPI with base year 1995) includes the amount paid for all common stock, common stock equivalents, preferred stock, debt, options, assets, warrants and stake purchases made within six months of the announcement date of the transaction. Liabilities assumed are included in the value if they are publicly disclosed. If a portion of the consideration paid by the acquirer is common stock, the stock is valued using the closing price on the last full trading day prior to the announcement of the terms of the stock swap. *Cross border* mergers are mergers where the acquiring and acquired companies stem from different nations. *Horizontal* mergers are defined as mergers between two companies with sales in the same primary 4-digit SIC industry. *Vertical* mergers are mergers where at least 10% of the sales (purchases) of the primary 4-digit industry, to which one of the companies belongs, must go to (come from) the industry to which the other belongs. We use the 1992 US input-output table. *Conglomerate* mergers consist of all mergers, which are neither horizontal nor vertical.

Panel B of Table 2 presents means of the distributions of sales, profits and profit to assets ratios for the acquired and acquiring companies in our sample. Profits are measured before interest and taxes (COMPUSTAT item 18), net sales are item 12, and total assets are item 6. Again all variables are deflated by the Consumer Price Index with base year 1995.

Table 2

Panel B. Characteristics of Acquiring and Target Companies

	Number of Obs.	Sales		Profits		Profit rate

United Kingdom	379	2,162.1	329.7	110.53	10.89	0.066	0.039
Continental Europe	172	4,644.2	729.6	169.86	24.58	0.035	0.033
Japan	16	4,349.1	876.1	165.10	26.47	0.011	0.030
Australia/N.Zealand/Canada	172	1,940.8	391.9	93.45	15.53	0.024	0.027
Rest of the World	47	2,132.4	443.0	157.64	22.88	0.052	0.013
All mergers	2,753	2,198.0	355.3	108.25	11.53	0.034	0.023

Note: The sample includes those mergers where we have all the relevant data for year t . Sales are average sales in million 1995 USD, profits are average profits before interest and taxes in million 1995 USD. The profit rate is profits before interest and taxes divided by total assets.

On average the acquired companies are just 16 percent of the size of the companies, which buy them and make only around a tenth of the profits. In the United States, the United Kingdom and Continental Europe the acquired firms are less profitable than their buyers, in Japan, Australia, Canada, and New Zealand they are more profitable. In the rest-of-the-world subsample, the acquired companies are much less profitable than their buyers.¹¹

III. Overall Results

A. Full Sample

In this section we present the main results for our full sample and for different subsets of mergers to see whether mergers on average have increased profits and sales or reduced them. In the following

section we look more closely at the mergers that have increased profitability to see whether the changes appear to be due to increases in efficiency or market power.

Table 3

Panel A: Effects of mergers for full sample

Years after the merger	Number of Observations	Difference in Mn \$	Profits p-value	% Positive	Difference in Mn \$	Sales p-value	% Positive
t+1	2,704	5.91	0.062	57.0%	-214.16	0.000	51.5%
t+2	2,274	11.11	0.009	57.2%	-382.81	0.000	49.5%
t+3	1,827	10.79	0.056	54.8%	-549.59	0.000	46.4%
t+4	1,517	19.68	0.007	57.8%	-633.46	0.000	46.3%
t+5	1,250	17.81	0.046	57.6%	-714.04	0.000	44.6%

Panel A of Table 3 presents our findings for the full sample of companies. The size of the sample declines as we move away from the date of the merger because companies disappear from the data set.¹² The profitability numbers consist of the difference in year $t+n$ between the actual profits of the combined firm and its projected profits in this year. Thus a negative number implies a decline in profits. The mean difference between actual and projected profitability is positive in all five years after the mergers, and is significant in every year at the 10 percent level, or better. The \$17.8 million constitutes a difference between actual and projected profits of 8.2 (0.20) percent of the profits (assets) of the average acquirer in the sample in year $t+5$.

The results for sales are again the difference between the actual and projected values for the combined companies. The mean difference in sales is negative in every year and continuously increases in absolute value through year 5. Five years after the mergers, the average acquiring firm had sales that were \$714 million lower than their projected value. This constitutes a difference between actual and projected sales of 14.5 percent of the sales of the average acquirer in the sample in year $t+5$. The last column in each set of results gives the fraction of the sample for which the change was positive. While a majority of mergers led to higher actual profits than those predicted, the reverse was true for sales.

B. Results by Country

Panel B reports the comparable figures by country or country group. The United States makes up a substantial fraction of the overall sample and so it is not surprising to find the pattern of results for it resembling that of the full sample as just discussed. Profits are higher than predicted in every post-merger year, although only three of the five differences are significant at the 10 percent level for the US. Actual sales are significantly less than predicted in every post-merger year. In percentage terms we predict that mergers increase profits by 8.1% (0.17%) of the profits (assets) of the average acquirer in the USA and decrease sales by 14.8% five years after the merger.

Essentially the same pattern can also be observed for the United Kingdom. Actual profits are greater than projected profits in all five years, although the difference is statistically significant in only the first post-merger year. Actual sales fall short of their projected values in all 5 years after the mergers, with all of the declines significant at conventional levels.

The pattern of results for Continental Europe is very similar to that for the USA and UK. The differences between actual and projected profitability are all positive, but the only significant difference is for the fourth post-merger year. Sales fall short of their projected values in every year and four of the five differences are statistically significant at the 5 percent level.

The results for Japan are somewhat different than those already discussed. Three of the five profit comparisons are negative, while sales are greater than predicted for the first time in two of the five post-merger years. Our sample for Japan is quite small, however, and none of the differences is statistically significant.

The results for Australia, New Zealand and Canada resemble those for the US, UK and Continental Europe in so far as actual sales fall short of predicted sales in all five post-merger years with three of the short falls being significant at the 10 percent level or better. The post-merger profit differences are also generally insignificant, as was the case for the UK and Western Europe, although in the case of Australia, New Zealand and Canada the post-merger profits of the merging firms tend to be less than those predicted for them, and one of these differences is significant at the 10 percent level.

Table 3

Panel B. Effects of mergers by country/country groupings

Years after the merger	Number of Observations	Profits			Sales		
		Difference in Mn \$	p-value	% Positive	Difference in Mn \$	p-value	% Positive
United States of America							
t+1	1,950	3.735	0.307	57.0%	-174.495	0.000	52.8%

t+5	15	-41.621	0.740	73.3%	-2328.611	0.187	46.2%
Australia/New Zealand/Canada							
t+1	165	-3.275	0.801	45.5%	-175.353	0.130	47.9%
t+2	129	-27.001	0.093	45.6%	-357.068	0.087	51.2%
t+3	101	-9.984	0.640	55.4%	-686.854	0.014	44.6%
t+4	79	5.862	0.858	54.3%	-962.244	0.016	48.1%
t+5	66	-33.577	0.308	47.0%	-805.393	0.121	39.4%
Rest of the world							
t+1	42	26.539	0.296	51.2%	-346.740	0.106	45.2%
t+2	35	71.808	0.086	61.8%	-237.196	0.174	42.9%
t+3	25	44.931	0.377	65.2%	-880.127	0.018	40.0%
t+4	22	93.866	0.153	89.5%	-577.552	0.223	50.0%
t+5	15	115.937	0.250	64.3%	-281.547	0.390	46.7%

Note: "Difference in Mn \$" is the difference between actual and projected profits or sales as obtained by equations (4) and (7) in 1995 million USD. A positive number therefore implies that the merger increased profits or sales, a negative number implies that the merger decreased profits or sales. "P-value" is the probability that the observed differences are zero (2-sided test). "% Positive" is the percentage of positive differences between actual and projected values.

The pattern of results for the remaining countries also resembles that for the US, UK and Continental Europe. Profit differences are positive in all five years, but are usually insignificantly different from zero. Sales differences are again consistently negative, although only one of these is statistically significant

Thus, the results by country and country group tend to resemble one another by and large. Differences between actual and projected profits tend to be positive but often are not significantly different from zero. Differences between actual and projected sales tend to be negative and often significantly so.

The lack of significant differences in results across countries can be further illustrated through an analysis of variance. Table 4 reports the results from a regression of the differences between actual and projected profits and sales on country category dummies for year $t+5$. An intercept has been included and the country dummies constrained to sum to zero, so that the coefficient on a country dummy represents the difference between its mean and that for the full sample (Suits, 1984).

Table 4. Analysis of variance in year $t+5$ by country categories

Country/country group	Profits		Sales	
	Difference in Mn \$	t-value	Difference in Mn \$	t-value
Average	17.8	2.00	-714.0	6.63
USA	-0.4	0.33	-16.2	0.70
UK	6.3	0.38	168.3	1.13
Continental Europe	24.5	0.37	47.6	0.55
Japan	-59.4	0.85	-1615.0	1.83
Aus/NZ/Can	-51.4	1.32	-91.4	0.45
Rest of the world	98.1	1.26	432.5	0.63
Adjusted R ²	-0.0006		0.0003	
Number of Observations	1,250		1,250	

Note: "Average" denotes the overall average value of the difference of actual and projected profits or sales. All other coefficients are differences from this average.

For the full sample, the mean difference between actual and predicted profits in year $t+5$ is positive and significant at the 5 percent level. No country category's mean is significantly different from that of the full sample. The mean difference between actual and predicted sales is negative and significant at the one percent level. All country means are insignificantly different from the sample mean

except for Japan, whose mean difference in sales is significantly less than the sample mean, although only at the 10 percent level.

C. Results by Sector and Type of Merger

In Panels A and B of Table 5 we have separated mergers into the manufacturing and service sectors, and then within these divided them into horizontal, vertical and conglomerate mergers. Mergers in the manufacturing sector tend to be less profitable than in the service sector. All 15 entries in the service sector are positive, while six of the 15 are negative in the manufacturing sector. The differences between actual and predicted sales are uniformly negative except for vertical mergers in the service sector, where two of the differences are positive.

Table 5. Effects of mergers by sector

Panel A. Effects of mergers in the manufacturing sector by category

Years after the merger	Number of Observations	Profits			Sales		
		Difference in Mn \$	p-value	% Positive	Difference in Mn \$	p-value	% Positive
Horizontal mergers							
t+1	411	-8.006	0.370	51.3%	-180.323	0.002	47.1%

t+3	470	5.772	0.627	55.5%	-316.710	0.004	52.1%
t+4	368	22.877	0.088	63.1%	-492.849	0.001	50.0%
t+5	287	39.167	0.038	65.7%	-545.498	0.007	52.3%
Vertical mergers							
t+1	22	23.377	0.248	50.0%	-234.462	0.399	45.5%
t+2	19	9.967	0.543	52.6%	-11.693	0.919	42.1%
t+3	17	38.608	0.031	64.7%	48.534	0.929	41.2%
t+4	15	11.566	0.781	73.3%	-376.665	0.338	50.0%
t+5	8	104.254	0.013	100.0%	933.507	0.588	50.0%
Conglomerate mergers							
t+1	550	0.716	0.914	59.8%	-178.648	0.016	50.7%
t+2	465	14.446	0.095	60.6%	-406.578	0.001	48.4%
t+3	374	26.555	0.034	59.1%	-584.358	0.000	46.0%
t+4	309	33.924	0.059	59.9%	-735.722	0.000	47.2%
t+5	247	36.059	0.100	59.5%	-1112.637	0.000	40.1%

Note: The *manufacturing* sector includes all firms with SIC codes smaller than 4000, the *service* sector includes those firms with SIC code larger than or equal to 4000. See also the note to table 3.

Table 6 presents the results for an analysis of variance conducted in much the same way as in Table 4. Coefficients on the merger categories represent differences from the intercept. In year $t+5$, horizontal mergers in manufacturing are significantly more profitable than the average merger in manufacturing, which had a near zero difference between its actual and projected values (Panel A). Vertical mergers in manufacturing are significantly (at the 10% level) less profitable, on the other hand. In contrast, all three categories of mergers are equally profitable in the service sector (Panel B). The difference between actual and projected profits for the average merger in the service sector is significantly higher than for the average merger in manufacturing.¹³

Table 6Panel A. Analysis of variance in year $t+5$ in the manufacturing sector by merger categories

Category	Profits		Sales	
	Difference in Mn \$	t-value	Difference in Mn \$	t-value
Average	3.1	0.27	-660.0	5.19
Horizontal	38.7	2.07	464.1	2.25
Vertical	-91.4	1.82	-329.1	0.59
Conglomerate	-9.0	1.13	-164.7	1.87
Adjusted R ²	0.0066		0.0045	
Number of Observations	702		702	

Panel B. Analysis of variance in year $t+5$ in services by merger categories

Category	Profits		Sales	
	Difference in Mn \$	t-value	Difference in Mn \$	t-value
Average	38.7	2.75	-782.1	4.87
Horizontal	0.5	0.03	236.6	1.56
Vertical	65.5	0.57	1715.6	1.31
Conglomerate	2.6	0.17	-330.5	1.88
Adjusted R ²	-0.0031		0.0051	
Number of Observations	542		542	

Note: "Average" denotes the overall average value of the difference of actual and projected profits or sales. All other coefficients are differences from this average. See also the note to table 5.

Although actual sales fall short of predicted sales in all three categories for the manufacturing sector, the shortfall is significantly smaller for horizontal mergers. Thus, within the manufacturing sector, horizontal mergers appear to be considerably more successful than conglomerate and vertical mergers with respect to their effect on both profits and sales.

Within the service sector, vertical mergers exhibit the best performance in terms of sales, although the small number of vertical mergers makes the difference statistically insignificant. Horizontal mergers still produce smaller shortfalls between actual and projected sales than do conglomerate mergers.

Thus, we conclude that mergers in the service sector are generally more successful than those in manufacturing, at least as far as their effects on profitability are concerned, and that horizontal mergers have more favorable effects on sales than do conglomerate mergers in both sectors, and on profits in manufacturing.¹⁴

Table 7

Effects of domestic and cross-border mergers

Years after the merger	Number of Observations	Difference in Mn. \$	Profits		Sales		
			p-value	% Positive	Difference in Mn. \$	p-value	% Positive
Cross Border mergers							
t+1	429	16.136	0.121	58.3%	-385.824	0.000	48.1%
t+2	336	15.727	0.170	58.3%	-555.023	0.000	47.3%
t+3	286	3.886	0.803	53.8%	-871.451	0.000	44.9%
t+4	236	37.202	0.050	66.1%	-785.575	0.002	47.0%
t+5	183	41.826	0.132	62.8%	-867.729	0.022	46.2%
Domestic Mergers							
t+1	2288	3.986	0.214	56.8%	-182.953	0.000	52.1%

t+3	1544	12.067	0.046	55.0%	-490.591	0.000	46.6%
t+4	1281	16.454	0.036	56.3%	-605.429	0.000	46.1%
t+5	1064	13.689	0.141	56.7%	-687.170	0.000	44.4%

Note. See the note to table 3.

D. The Effects of Cross-Border Mergers

Table 7 breaks the sample into cross-border and domestic mergers. We have at most 429 observations on cross-border mergers, and so the results for domestic mergers look a lot like those for the full sample. The same can more or less be said for the cross-border mergers. Mean differences between actual and projected profits are positive in all five post-merger years, but are significantly different from zero in only one of them. Mean differences between actual and projected sales are negative and significant in all five post-merger years. We tested for differences in the effects of cross-border mergers that were related to the origin of either the acquiring or target company, but did not find any significant differences. Cross-border acquisitions by (of) UK companies did not generate significantly larger changes in sales and profits than was true for other cross-border acquisitions, and the same was true for all other countries.

IV. Results: Market Power and Efficiency

Mergers that increase the efficiency of the merging firms should increase both their profits and their sales. Mergers that increase market power should increase profits and reduce sales. A merger, which reduces efficiency, should reduce both profitability and sales. In this section we attempt to increase our understanding of the causes and effects of mergers, by dividing our sample into subsets of mergers that either increase or reduce profitability.

Panel A1 of Table 8 reports the results for all mergers for which post-merger profitability changes are greater than those of the matching industries, while Panel A2 reports the figures for the mergers that reduced profitability relative to the control group. The mean difference between actual and projected sales is negative and significant in every post-merger year. The difference between actual and projected profits in year $t+5$ is more than \$ 150 million for profitable mergers, a difference of 70.0% (1.70%) percent of the actual profits (assets) of the average acquirer in the sample in year $t+5$. The difference between actual and projected sales in $t+5$ is \$ - 475 million, - 9.6 percent of the sales of the average acquirer in $t+5$. This is the pattern we expect for mergers that increase market power, and thus we conclude that the *average* profitable merger in our sample would appear to have increased market power.

Not surprisingly, actual sales for companies undertaking unprofitable mergers (Panel A2) fall way below their projected values. We predict that had the acquiring firms not undertaken these mergers they would have had 72.3% more profits and 20.8% more sales than they actually had in year $t+5$. These mergers are unsuccessful in both dimensions and imply that they lowered efficiency.

In Panel B1 of Table 8 the results are reported for the highest quartile of mergers ranked by the difference between actual and projected profits. The average profit changes are roughly three times as large as those in Panel A1. Mean actual sales continue to fall short of their projected values in every year after the mergers. All sales comparisons are highly significant. In Panel B2 of Table 8 the results are reported for the lowest quartile of mergers ranked by changes in profits. These mergers appear as unmitigated disasters.

Table 8. Tests for Efficiency and Market Power Effects

Panel A1. Mergers with profits changes above zero

Years after the merger	Number of Observations	Profits Difference in Mn. \$	Sales Difference in Mn. \$	p-value
t+1	1,512	76.129	-92.148	0.013
t+2	1,276	97.129	-247.630	0.000
t+3	981	117.517	-328.543	0.000

t+5	336	-160.265	-1138.591	0.000

Panels C, D and E in Table 8 divide mergers with changes in profitability above the matching industries into the horizontal, vertical and conglomerate categories. The first thing to note is that all three categories of successful mergers exhibit roughly similar increases in profitability. The mean differences between actual and projected profits tend to get larger as one moves away from the mergers, and fall roughly in a range from \$ 150 to \$160 million in year $t+5$.

The mean differences between projected and actual sales for companies undertaking profitable horizontal and conglomerate mergers are negative in all five years following the mergers. Thus, the average merger falling in both categories appears to result in an increase in market power. In contrast the

mean difference between projected and actual sales for firms undertaking vertical mergers is negative in only year one. Although none of the other four entries is statistically significant, the results for profitable vertical mergers are *weakly* consistent with their increasing efficiency.

Panels F, G and H in Table 8 parallel C, D and E for mergers that lowered profitability. All 15 post-merger sales comparisons are negative, with all differences for horizontal and conglomerate mergers being statistically significant, as were two for vertical mergers. The average unprofitable merger fits the pattern we anticipate for efficiency reducing mergers regardless of what type of merger it is.

One might expect mergers between small firms to be more likely to increase efficiency by creating economies of scale and scope, while mergers between large firms would be more likely to increase market power. These conjectures would lead us to expect sales increases following profitable mergers between small companies, and sales decreases following profitable mergers between large companies. Our final test for the effects of mergers splits our sample into small and large acquirers, and profitable and unprofitable mergers.¹⁵

The results of these tests are reported in Table 9. The mean differences between actual and projected sales are positive and significant in all five post-merger years for the small firms making profitable mergers (Panel A). These differences suggest that profitable mergers of small firms increase sales by around \$ 150 million or 25.0% relative to the average small acquirer's size in year $t+5$, while profits nearly double. This pattern accords with our prediction for efficiency enhancing mergers and is the first time that actual sales have exceeded their projected values on average in each of the five post-merger years. These results strongly suggest that these mergers increased the efficiency of the merging firms.

Table 9

Panel A. Mergers with profits changes above zero by size

I. Small Firms

Years after The merger	Number of Observations	Profits Difference in Mn. \$	Sales Difference in Mn. \$	p-value
t+1	766	20.440	54.953	0.000
t+2	642	27.947	72.190	0.000
t+3	476	36.465	83.328	0.001
t+4	418	40.155	129.245	0.000
t+5	349	47.001	148.724	0.002

II. Large Firms

t+1	746	133.310	-243.194	0.001
t+2	634	167.294	-571.486	0.000
t+3	505	193.925	-716.762	0.000
t+4	439	236.070	-902.450	0.000
t+5	357	255.298	-1085.415	0.000

Panel B. Mergers with profits changes below zero by size

I. Small Firms

t+1	610	-28.854	-59.829	0.001
t+2	514	-30.951	-88.808	0.000
t+3	453	-43.943	-128.520	0.009
t+4	356	-55.022	-105.590	0.004
t+5	288	-53.384	-65.567	0.215

II. Large Firms

t+1	582	-140.806	-692.914	0.000
t+2	484	-171.866	-1051.408	0.000
t+3	393	-194.135	-1586.702	0.000
t+4	304	-239.117	-1911.873	0.000
t+5	256	-274.339	-2101.856	0.000

Note: The full sample was first divided into "small" and "large" companies using the sales median of acquiring firms in year $t-1$ as the dividing line. These two samples were then subdivided on the basis of whether profits were greater or less than their projected values.

In contrast mean differences between actual and projected sales are negative and significant in all five post-merger years for the large firms making profitable mergers. These differences suggest that profitable mergers of large firms decrease sales by around \$ 1 billion or 10.7% relative to the average large acquirer's size in year $t+5$, while the change in profits is 60.7% of the profits of the average large acquirer in $t+5$. These differences accord with our prediction for market power enhancing mergers. The average profitable merger among small firms appears to increase their efficiency, the average profitable merger by a large firm appears to increase its market power.

The results of Panel B of Table 9 are for the firms, which undertook unprofitable mergers. Here we see for both size classes consistent declines in post-merger sales. Unprofitable mergers by both small and large companies tend to be the result of reduced economic efficiency.

V. Comparisons with Previous Results in the Literature

The results reported above with respect to the effects of mergers on profitability and sales are broadly consistent with those obtained by others. In a recent survey of the literature Mueller (1997) summarized the results from 20 studies drawn from 10 countries over the post-World War II period that generally followed the methodology that we have employed here to determine the effects of mergers on profitability, namely compared actual post-merger profits with those predicted using a control group.

The most ambitious of all of the studies in terms of sample size, time span, and care in handling the data was that of Ravenscraft and Scherer (1987) for the United States. They concluded that the profitability of acquired firms declined after they were acquired. On the other hand, Healy et al. (1992) found a significant increase in the pre-tax cash flows of the companies involved in the 50 largest mergers between 1979 and 1984 implying that the largest mergers in the U.S. during the early 1980s did increase either the market power or the efficiency of the merging firms.¹⁶ Our results suggest that the profit increases that Healy et al. observed were mostly due to increases in market power.

The largest study of mergers in the UK (Meeks, 1977) concluded as did Ravenscraft and Scherer that mergers reduced the profitability of the merging companies. Other studies for the UK have, however, reached the opposite conclusion (Cosh, Hughes and Singh, 1980). Although the preponderance of evidence for the UK suggests that mergers tend to reduce profitability (Hughes, 1989), not all studies have reached this conclusion.

No distinct pattern emerges in the studies from other countries. Profit increases were observed in Canada (Baldwin, 1991) and Japan (Ikeda and Doi, 1983), profit decreases in Holland (Peer, 1980) and Sweden (Ryden and Edberg, 1980). In all other countries the differences were statistically insignificant. Where mergers seem to result in profit increases in one country (e.g., Germany), they result in declines in another (e.g., France). Thus, our overall finding that the actual post-merger profits of merging companies are in many cases insignificantly different from their predicted values is in general accordance with the findings of previous studies. Where we perhaps differ from them is that we have observed a greater preponderance of positive and significant profit changes following mergers.

Our findings with respect to post-merger changes in sales for the surviving firms also accord with the main results reported in the literature. Since we project a merging company's sales using the median

sales of a non-merging company in the same industry, one might expect that relative declines in sales will translate into declines in market shares. Three studies of the effects of mergers on market shares exist. Goldberg (1973) observed insignificant changes in market shares for a sample of 44 advertising intensive firms over an average of 3 1/2 years following their undertaking a merger. Mueller (1985) observed significant *declines* in market shares for a sample of 209 manufacturing companies over an average of 11 years following the mergers. Baldwin and Gorecki (1990) found significant declines in market shares for plants acquired in horizontal mergers, but no significant changes for plants acquired in other sorts of mergers. They concluded that their results were consistent with the mergers having increased market power.

Nine studies that measured changes in the growth rates of merging firms following the mergers using either their industries or matched non-merging firms as control groups found either that the mergers produced no significant change in growth rates [see McDougall and Round (1986) for Australia; Kumps and Wtterwulghé (1980) for Belgium; Jenny and Weber (1980) for France; Cable, Palfrey and Runge (1980) for Germany; Ryden and Edberg (1980) for Sweden; Cosh, Hughes and Singh (1980) for the United Kingdom; and Amel and Rhoades (1989) for acquired U.S. banks], or significant declines [Peer (1980) for Holland and Mueller (1980b) for the United States]. Thus, no study of which we are aware has found significant increases in either the internal growth rates of merging companies or their market shares following their acquisitions, and several have reported significant declines. Our general finding of smaller sales for merging companies than are projected using the sales changes of the median nonmerging firm in the merging companies' industries is consistent with these results from the literature.

VI. A Categorization of Mergers According to Their Effects on Market Power and Efficiency

We begin this paper by stating that mergers can be divided into three broad categories: those that increase profits by increasing market power, those that increase profits by increasing efficiency and those that reduce profits and efficiency. In Table 1 we categorized these and the other logically possible consequence of mergers. Table 10 summarizes the results of our study by reporting the fractions of mergers that fall into each of the four categories. The first entry in each cell gives the percentage of all acquisitions by small companies falling into this cell, the second entry is for large acquirers, and the third

is for all mergers regardless of size. Cell 1 reveals that 29.1 percent of the mergers in our sample resulted in increases in both sales and profits, and thus met our criterion for efficiency increasing mergers. A larger fraction of mergers by small firms (34.7%) satisfied our criterion for an efficiency-increasing merger than was true for large firms (23.4%) (difference significant at the one percent level).

Table 10: Classification of mergers by firm size in year $t+5$ (Percent of mergers)

		$\Delta\Pi>0$	$\Delta\Pi<0$
		1	3
$\Delta S > 0$	Small	34.7	17.5
	<u>Large</u>	<u>23.4*</u>	<u>12.7*</u>
	All	29.1	15.1
		2	4
$\Delta S < 0$	Small	20.4	27.4
	<u>Large</u>	<u>34.8*</u>	<u>29.1</u>
	All	27.6	28.2

Notes: $\Delta\Pi>0$ ($\Delta\Pi<0$) denotes that the mergers resulted in a profit increase (decrease) relative to year t and relative to industry and country peers. $\Delta S>0$ ($\Delta S<0$) denotes that the mergers resulted in a sales increase (decrease) relative to year t and relative to industry and country peers. The first number in each cell is for small firms (total sales less than the median in year $t-1$), the second number in each cell is for large firms (total sales more than the median in year $t-1$), and the third number in each cell is the overall proportion. A * means that the proportion of small firms is significantly different from the proportion of large firms at the 1 % level, two-sided test.

Roughly the same fraction of mergers reduced efficiency (cell 4) as increased it. Here, however, there was no difference related to size. Small firms were just as likely to undertake a merger that reduced both profits and sales as were large firms.

A slightly smaller fraction of mergers met our criteria for a market power increase than did so for an efficiency increase. As one expects, large firms accounted for a significantly larger fraction of market power increasing mergers (34.8%) than did small companies (20.4%). Thus, some 85 percent of the mergers in our sample fall into the three main categories "efficiency increasing", "efficiency reducing" or "market power increasing", and they are divided roughly equally across them.

These comparisons leave out the somewhat puzzling cell 3. As we noted in Section 1, this pattern of effects – sales rise and profits fall – is what one might expect of firms whose managers were size or growth maximizers. It is also what one would expect if the mergers led to a decrease in market power

using the same logic that we employ to determine increases in market power. Even if one uses this logic to classify mergers in cell 3 as socially beneficial, however, the fraction of beneficial mergers in our study (44.2) falls short of the fraction that is harmful because they either increase market power or reduce efficiency.¹⁷

VII. Conclusions

We believe that the present study is the first to determine the effects of mergers on efficiency and market power by first separating mergers into those that increase profits and those that reduce them, and then examining the patterns of sales changes following the mergers. Most previous studies have judged the consequences of mergers by examining their average effects on either the profits or sales of the merging companies. As the previous section suggests, our results using these tests are broadly consistent with what others have found. We find that 56.7 percent of all mergers result in higher than projected profits, but almost the same fraction of mergers results in lower than projected sales after five years. Both mean differences are significantly different from zero. Thus, using profits as the measure of success would lead one to conclude that the average merger was a success, using sales one would reach the opposite conclusion. By basing our judgement of the welfare effects of mergers upon criteria that look at both the sales and profits changes following mergers, we have been able to resolve this ambiguity. We predict profit increases and sales declines for mergers that increase market power. More than a fourth of all mergers exhibit this pattern, and this helps to explain why mergers look more successful, when one examines post-merger profits than for post-merger sales. If one categorizes mergers that increase market power or that reduce efficiency as welfare reducing, then a majority of the mergers taking place around the world over the last 15 years appear to be welfare reducing.

Our study is the largest cross-national comparison of the effects of mergers to date. In this respect one of our most interesting findings is how similar the post-merger patterns of profit and sales changes look across the different countries. We also did not find significant differences between domestic and cross-border mergers. Although individual mergers can have quite different consequences in terms of efficiency and market power, their effects do not appear to depend on the country origins of the merging companies.

NOTES:

1. We shall not distinguish between mergers and takeovers, but rather simply refer to all as mergers.
2. Let the industry demand schedule for a homogeneous product be $P = 1 - X$, where P is price and X is total output. Assume five firms with zero marginal costs. In a symmetric Cournot equilibrium each firm's output is $1/6$, and industry price is $1/6$. Each firm's sales and profits equal $1/36$. If following a merger between two firms all firms move to the perfect collusion point on the demand schedule, $P = 1/2 = X$, and industry profits and sales both equal $1/4$. If the merged company accounts for $1/4$ th of the industry's output, its post-merger profits and sales ($1/16$) exceed those of the two firms before the merger ($2/36$).
3. See, Ravenscraft and Scherer (1987), Mueller (1980a) and Healy et al. (1992).
4. Choosing as a control group the companies at the first and third quartiles of the size distribution and matching by size did not substantially change our findings. Our control group excludes firms that made mergers in the period $t-1$ to $t+5$, where t is the year of the merger. In the small fraction of cases where no control group was available for the respective industry and country or country group, we take the median firm in the whole manufacturing/service sector of the respective country/country group.
5. Two biases might occur: If sales data are missing on additional mergers from t to $t+5$ we underestimate projected sales, if sales data are missing on spin- or sell-offs from t to $t+5$ we overestimate projected sales. Additional mergers occur more often than divestitures, while divestitures are larger on average. Thus, the two biases potentially offset each other.
6. Again, two biases occur which potentially offset each other: If the relevant profits data on additional mergers undertaken from t to $t+5$ are missing and taken over profits are positive (which they are on average), we underestimate projected profits. If the relevant profits data on divestitures undertaken from t to $t+5$ are missing and spun or sold off profits are positive (which they are on average), we overestimate projected profits.
7. Symmetrically we define a spin- or sell-off as a transaction where more than 50% of the equity are disposed off. We use the term "divestitures" interchangeably.
8. A table summarizing the characteristics of divestitures is available upon request. In short, our database covers 9,659 completed divestitures worldwide from 1981 to 1998, 31.4% of these were cross border deals, 37.0% horizontal, 4.3% vertical, and 58.7% conglomerate. The average deal value was \$ 181 million.
9. We could match 6,616 divestitures to these databases aggregated to 4,666 divestiture years.
10. In Tables 3-9 we drop the left and right one percent of the distribution in each (sub)sample.
11. Summary statistics on divestitures (available upon request) reveal that divested units are larger and less profitable than acquired firms.

-
12. Remember our last year is 1998, thus mergers having taken place in 1993 are the last mergers for which we have data until year $t+5$, mergers having taken place in 1994 are in our sample only up to year $t+4$, mergers of year 1995 up to year $t+3$ and so on.
 13. Test results are available from the authors upon request.
 14. We also tested for significant differences in the effects of mergers depending on the industry of the acquiring companies. Almost no significant differences were found. The most interesting exceptions were for the chemicals and insurance industries. Mergers in these industries were followed by profit increases significantly above the sample mean, and sales declines below the mean. The patterns of profits and sales changes following mergers in the chemicals and insurance industries strongly resemble those that we associate with market power increases.
 15. The full sample was first divided into "small" and "large" companies using the median sales of acquiring firms in year $t-1$ as the dividing line. These two samples were then subdivided on the basis of whether profits were greater or less than their projected values. "Large" firms have average sales (profits) of \$ 5,713 (264) million and "small" firms have average sales (profits) of \$ 341 (18.1) million in year $t-1$. The average deal value of transactions involving "large" acquirers is \$ 667 million, while the average deal value involving "small" acquirers is \$ 103 million.
 16. Ravenscraft and Scherer also reported that "mergers among equals" – which is to say between two large firms – were more profitable than the average merger in their sample.
 17. Of course, some of the differences between actual and projected profits and sales that we record are small and *economically* insignificant. Thus, some of the mergers falling into each category might be judged to have resulted in small and insignificant increases in market power, etc. An alternative way to proceed would be to define an additional category – no significant difference – where significant difference is interpreted as an economically meaningful difference between the actual and projected values. We made such a classification using a one percentage point difference in profits relative to assets and a 10 percent difference in sales as our criteria for significant difference. Using these criteria, three percent of the mergers fell into the no difference category for both profits and sales, and 60 percent of all remaining mergers fell into the three main categories identified in Table 1, with the division among them remaining roughly equal – 20 percent in each cell. Thus, one's judgement as to the *relative* proportions of socially beneficial and harmful mergers is not affected by introducing an additional, no-difference category.
