ABSTRACT. In this paper, we prove a new version of the Second Welfare Theorem for nonconvex economies with a finite number of agents and an infinite number of commodities, that is when the preference correspondences are not convex-valued and/or when the total production set is not convex. For this kind of nonconvex economies, a recent result, obtained by one of the authors, introduces conditions which, when applied to the convex case, give for Banach commodity spaces the well-known result of decentralization by continuous prices of Pareto-optimal allocations under an interiority condition. In this paper, in order to prove a different version of the Second Welfare Theorem, we reinforce the conditions on the commodity space, assumed here to be a Banach lattice, and introduce a nonconvex version of the properness assumptions on preferences and the total production set. Applied to the convex case, our result becomes the usual Second Welfare Theorem when properness assumptions replace the interiority condition. The proof uses a Hahn-Banach Theorem generalization by Borwein and Jofré which allows to separate nonconvex sets in general Banach spaces.

JEL Classification numbers: D51, D6

Keywords and phrases: second welfare theorem, nonconvex economies, Banach spaces, subdifferential, Banach lattices, properness assumptions.

1. INTRODUCTION

For convex economies with given technological and resource limitations, individual needs and tastes, the second welfare theorem states that every Pareto optimal allocation can be supported by a non-zero price vector such that each consumer minimizes his expenditure over his preferred set and each firm maximizes its profit. Translated in mathematical terms, it means that the supporting price vector belongs to the normal cone (in the sense of convex analysis) to the total production set at the production component of the optimal allocation while its opposite belongs to the normal cone to each preferred set at the corresponding consumption component of the allocation.

Date: August 4, 2005.

*This work was partially supported by Nucleo Complex Engineering System. The successive versions of the paper were partly prepared during visits of Alejandro Jofré to CERMSEM and of Monique Florenzano and Pascal Gourdel to the Centro de Modelamiento Matemático. The hospitality of both institutions and the support of the french Coopération régionale Cone Sud are gratefully acknowledged. The authors thank Ali Khan for stimulating exchange of ideas and literature, Roko Aliprantis, Jean-Marc Bonnisseau, Alain Chateauneuf, Roger Guesnerie, Filipe Martins Da Rocha, Moncef Meddeb, B. Mordukovich, Lionel Thibault and Rabee Tourky for valuable discussions.

In an infinite dimensional setting, that is for economies with infinitely many commodities, the result first appeared in a seminal paper of Debreu (1954) [10] where the commodity space is a topological vector space. Besides convexity hypothesis, a key assumption of Debreu's result is that the total production set of the economy has a nonempty interior, an assumption strongly related by him with free-disposal in commodities, which clearly reduces the application of the result to ordered topological vector commodity spaces whose positive orthant has a nonempty interior. A simple look to Debreu's proof, based on the Hahn-Banach theorem, allows for noticing that the interiority assumption could be likewise done for anyone of the preferred sets. However, given the assumptions currently used for guaranteeing the existence of Pareto optimal allocations, such an assumption would equally be suited for commodity spaces whose positive cone has a nonempty interior but, as previously, would prevent any application of the result to a number of commodity spaces which have been found of economic interest. This limitation explains why, thirty two years after, Debreu's result was revisited by Mas-Colell (1986) [23] who replaces Debreu's interiority condition by the so-called properness assumptions on preferences and production, at the cost of strengthening the assumptions made on the commodity space which is assumed in [23] to be a topological vector lattice and on the consumption sets restricted to coincide with the positive orthant. As in Debreu [10], the weak optimum is supported by a non-zero, continuous linear functional p called "valuation functional". Moreover, $p(\omega) > 0$ if the total initial endowment, $\omega > 0$, is the common properness vector.

Recall that the interest for nonconvex economies, an old interest in Economics, arises on the production side from the consideration of increasing returns to scale and/or of certain externalities. On the consumption side, besides all forms of indivisibilities that we postulate away in this paper, nonconvex preferences correspond, as in Starr [31], to anti-complementarities¹ between commodities, for example to non-aversion to risk for agents facing uncertainty. The reasons for considering nonconvex models in an infinite dimensional commodity space are not different. For a general study of the infinite dimensional spaces of interest in Economics, we refer the reader to the survey of Mas-Colell and Zame [24] in the Handbook of Mathematical Economics. Let us simply observe here that in a dynamic setting, technological change and the introduction of new goods and production processes should contribute to yield a nonconvex total production set. In the same way, whatever may be the formalization of uncertainty with an infinite dimensional space of states of nature (probability space or simply measurable space), the study of finance models with non convex preferences should allow to take into account the fact that a substantial fraction of the investors exhibit some uncertainty (or risk) appeal.

When the preferred sets and/or the aggregate production set are nonconvex, it is not always possible to find prices for which consumer and producer choices at a Pareto optimal allocation are truly optimal. An equilibrium notion is then defined where prices are such that choices satisfy the first order conditions for optimality written in terms of normal cones to the preferred and production sets. As well-known, even in a finite dimensional setting, several notions of normal cone have been used. Each one has a different implication for the economic significance of the decentralization result.² But whatever be the used notion of normal cone, on the production side, the first order conditions are interpreted as pricing rules for the nonconvex firms allowing the economy as a whole to achieve efficient allocations through a mechanism that is as decentralized as

¹Arrow-Hahn [4] write that "some pairs of commodities may be antagonistic in consumption".

²Think for example of Clarke's normal cone used by most of authors to study equilibrium in production with increasing returns, compared to the one used by Guesnerie [12] that can be interpreted in terms of cost minimization if the set of input combinations that produce a given level of output is convex.

possible. On the consumption side, when preferences are not convex valued, rather than first order conditions, the Shapley-Folkman theorem is often used by economists to exhibit an approximate expenditure minimizing behavior (see [3] and its references). In Jofre-Rivera [18], an analogue interpretation is given using the normal cone defined in their paper.

In an infinite dimensional setting, several works on decentralization of Pareto optimal allocations have solved the question of its extension to nonconvex economies (for recent results at a level of generality comparable to Debreu [10] or Mas-Colell [23], see mainly Bonnisseau-Cornet (1988) [5], Mordukhovich (2001) [26], Jofré (2000) [17]). The three above quoted papers differ by the commodity space they consider: a topological vector space in [5], an Asplund space³ in [26], a general Banach space in [17], and the normal cone used for generalizing the normal cone of convex analysis: Clarke's normal cone in [5], Mordukhovich's normal cone in [26], Ioffe's normal cone in [17]. In view of convexity of Clarke's tangent and normal cones, the separation tool used in [5] is the Hahn-Banach theorem, while [26] and [17] use variational generalizations of the Hahn-Banach theorem, respectively an "extremal principle" due to Mordukhovich-Shao [27] and a "nonconvex separation property" due to Borwein-Jofré [6]. [17] and [26] have in common an asymptotic (net demand qualification) condition which, used jointly with the separation argument, allows to prove "viscous" or "approximate" versions of the second welfare theorem. When an additional condition, called compactly epi-Lipschitzianity, is introduced on one of the preferred or production sets then the approximate decentralization becomes exact, that is, there exists a price vector belonging to a suitable normal cone (or its opposite) to the preferred and production sets at the corresponding component of the Pareto optimal allocation. The three papers have in common⁴ this assumption which generalizes to the non-convex case the interiority condition of Debreu [10]. In its own setting, each one is up to now the best extension of Debreu's paper.⁵

The aim of this paper is to extend Mas-Colell's result to nonconvex economies defined on Banach commodity spaces. We introduce properness conditions on preferred and production sets analogue to the ones used by Mas-Colell. They can be given an analogue interpretation and allow to 'support with prices local weak Pareto optimal allocations. Properness assumptions require (in the proof of our result) a topological vector lattice structure on the commodity space and consumption sets restricted to the positive orthant, in order to use the decomposition property of vector lattices and solidness of zero neighborhoods. It then appears that properness conditions joint with a non-satiation assumption, natural in this problem, give us for free the the asymptotic condition used in [5], [26], [17], so that we can apply the "viscous" separation property of Borwein-Jofré [6]. Also thanks to the properness assumptions, we can go from an approximate to an exact decentralization result without assuming any (compactly) epi-Lipschitzianity of one of the preferred or production sets. The supporting vector price is obtained in any normal cone satisfying some convenient properties.

It is worth noticing that preferences need not be transitive or complete and are defined for each consumer by (strictly) preferred sets. We do not make any monotonicity assumption on preferences or free-disposal assumption on production and get a decentralization result as well for production

³Asplund spaces are Banach spaces on which every continuous convex function is generically Fréchet differentiable. Particular examples are all reflexive Banach spaces and all Banach spaces with separable duals.

⁴In [5], compactly epi-Lipschitzianity is replaced by epi-Lipschitzianity, a stronger assumption which guarantees also that the asymptotic condition is satisfied.

⁵We do not include in this comparison papers of historical interest as Khan-Vohra (1988) [20] and Khan (1991) [19] which use in several respects stronger assumptions. We also omit Mordukhovich (2000) [25] which extends and slightly generalizes Jofré (2000) to several local Pareto optimality notions.

economies as for pure exchange economies. As we strengthen some assumptions and weaken some other ones, this result should be considered as a complement more than a substitute to Jofré's paper. Applied to the convex case, it has as corollary the usual second welfare theorem in Banach commodity lattices when properness assumptions replace the interiority condition.

The paper is organized as follows. Section 2 recalls definitions and properties of subdifferential and normal cone which will be used later and, in order to prepare the comparison with previous results (see Remark 3.7), definitions and properties of (compactly) epi-Lipschitz sets. Section 3 describes the model, posits the main assumptions and states the main results. Section 4 is devoted to proofs.

2. MATHEMATICAL PRELIMINARIES

Let X be a Banach space, X^* its topological dual. For $x \in X$ and $p \in X^*$, we note $p \cdot x$ the evaluation $p(x)$. In what follows, B and B^* denote respectively the open unit-ball of X and the open unit-ball of X^* , $B(x, \varepsilon)$ the open ball with center x and radius ε . Given a set $S \subset X$, $d_S(x)$ denotes the distance from x to S defined in the given norm by

$$d_S(x) := \inf_{y \in S} \|x - y\|$$

and

$$\chi_S(x) := \begin{cases} 0 & \text{if } x \in S \\ +\infty & \text{if } x \notin S \end{cases}$$

denotes the indicator function of S ; $\text{int } S$, $\text{cl } S$ and $\text{bd } S$ denote the interior, the closure and the boundary of S .

If A is a subset of X^* , $\text{cl}^* A$ denotes the closure of A for the weak-star topology $\sigma(X^*, X)$.

2.1. Subdifferentials and normal cones. By a subdifferential, we mean any set-valued mapping which associates with every lower semicontinuous extended-real-valued function f defined on X and any $x \in X$ a set $\partial f(x) \subset X^*$. For any $f, g : X \rightarrow \mathbb{R}$ locally Lipschitz functions and any point $x \in X$, we require the following list of properties:

- (a) $\partial f(x) = \emptyset$ when $x \notin \text{dom}(f)$;
- (b) $\partial f(x) = \partial g(x)$ if f and g coincide in a neighborhood of x ;
- (c) ∂f is the classical subdifferential whenever f is a convex function;
- (d) if f and g are locally Lipschitz and if x is a local minimum of $f + g$, then $0 \in \partial(f + g)(x) \subset \partial f(x) + \partial g(x)$;
- (e) if k is the constant of Lipschitz of f near x , then $\|p\| \leq k$ for all $p \in \partial f(x)$;
- (f) given closed subsets Z_1, Z_2 of X , the function $h : Z_1 \times Z_2 \rightarrow \mathbb{R}$ defined by $h(z_1, z_2) = f_1(z_1) + f_2(z_2)$ satisfies $\partial h(z_1, z_2) \subset \partial f_1(z_1) \times \partial f_2(z_2)$;
- (g) given $A : X \rightarrow Y$, a bounded linear operator defined from a Banach space X onto a Banach space Y , A^* its adjoint, $\lambda > 0$, and $b \in Y$, if $f(x) = \lambda g(Ax + b)$ where g is locally Lipschitz, then $\partial f(x) = \lambda A^* \partial g(Ax + b)$.

The subdifferential is said to be *robust* on a class of functions if, for any function f of this class, the set-valued mapping $x \rightarrow \partial f(x)$ has a closed graph in $X \times X^*$ when X and X^* are respectively endowed with the norm-topology and the weak-star topology $\sigma(X^*, X)$.

If $S \subset X$, the *normal cone* to S at $x \in S$ associated with the given subdifferential is defined as the subdifferential of the indicator function of S at x :

$$N_S(x) = \partial \chi_S(x).$$

That the previous list of properties, sufficient for our purposes, is nonvacuous and consistent is verified by the fact that a number of subdifferentials, in particular the approximate subdifferential, as defined by Ioffe in [16], satisfy (a)–(g)⁶. Moreover, the approximate subdifferential is robust on locally Lipschitz functions, a property which plays a fundamental role in our result. If X is Asplund and f Lipschitz near x , the approximate subdifferential of f at x coincides with Mordukhovich's subdifferential when Mordukhovich's subdifferential is robust, in particular if X is reflexive or separable (see Section 9 of [27]). If f is Lipschitz near x , Clarke's subdifferential of f at x is the weak-star closed convex hull of the approximate subdifferential of f at x (see Theorem 7.2 of [15]).

2.2. Epi-Lipschitz sets. We recall that a subset Z of a (nonnecessarily complete) normed space X is called *epi-Lipschitz at $z \in \text{cl } Z$ with respect to $d \in X$* if there exists some $\varepsilon_z > 0$, $\alpha_z > 0$ and $\delta_z > 0$ and a point (a direction) $d \in X$ satisfying

$$Z \cap (z + \varepsilon_z B) + t(d + \delta_z B) \subset Z, \quad \forall t \in [0, \alpha_z].$$

A set Z *epi-Lipschitz at z* if it is epi-Lipschitz with respect to some d . Finally, Z is *epi-Lipschitz* if it is epi-Lipschitz at every element z in $\text{cl } Z$.

The following proposition summarizes the properties of epi-Lipschitz convex sets in normed spaces.

Proposition 2.1 (Rockafellar [30]). *Assume that X is a normed space and Z is a subset of X .*

a) *If Z is epi-Lipschitz at some $z \in \text{cl } Z$, then $\text{int } Z$ is nonempty. If, conversely, $\text{int } Z$ is nonempty and Z is convex then Z is epi-Lipschitz.*

b) *Consequently, if $Z \subset Z'$, Z is epi-Lipschitz at some $z \in \text{cl } Z$ and Z' is convex then Z' is epi-Lipschitz.*

Proof. a) is proved in [5] in the case X is a topological vector space, for the corresponding notion of epi-Lipschitzianity.

The proof of b) is obvious. □

We will use in this paper a “viscous” separation theorem in Banach spaces obtained by Borwein and Jofré [6] using the Ekeland variational principle and the properties (a) – (f) of the subdifferential of the distance function. We recall now its statement.

Theorem 2.1. *Let Z_1, \dots, Z_n be closed subsets of a Banach space X and let $(\bar{z}_1, \dots, \bar{z}_n) \in Z_1 \times \dots \times Z_n$ be such that*

$$\sum_{i=1}^n \bar{z}_i \in \text{bd} \left(\sum_{i=1}^n Z_i \right).$$

There exists $c > 0$ such that for any $\varepsilon > 0$ there exist $z_i \in (\bar{z}_i + \varepsilon B)$ and $p^ \in X^*$ such that*

$$p^* \in \bigcap_{i=1}^n (\partial d_{Z_i}(z_i) + \varepsilon B^*) \quad \text{and} \quad 0 < c \leq \|p^*\| \leq 1.$$

⁶Proofs of the different properties for the approximate subdifferential can be found in [13] [14] [15] [16]. The reader has to be cautious with the fact that the terminology used evolves from one paper to another in the different papers of Ioffe quoted in our list of references.

3. THE ECONOMIC MODEL AND RESULTS

Let L be a Banach lattice, L^* be its topological dual. On L as commodity space, we consider an economy consisting of a finite set $M = \{1, \dots, m\}$ of consumers and, for the sake of simplicity, one producer. Each consumer i is described by a consumption set $X_i \subset L$, a preference correspondence $P_i : \prod_{k \in M} X_k \rightarrow X_i$, satisfying $x_i \notin P_i(x)$ for every $x \in \prod_{k \in M} X_k$. If $x \in X := \prod_{k \in M} X_k$, $P_i(x)$ is interpreted as the set of those consumptions in X_i which are (strictly) preferred by agent i to x_i when the consumption of each agent $k \neq i$ is equal to x_k . The set $Y \subset L$ is the (total) production set. The aggregate endowment is denoted by $\omega \in L_+$. To summarize, the economy \mathcal{E} is defined by the following list:

$$\mathcal{E} = (\langle L, L^* \rangle, (X_i, P_i)_{i \in M}, Y, \omega).$$

Let $\mathcal{A}(\mathcal{E})$ be the set of all *attainable allocations* of the economy \mathcal{E} , that is:

$$\mathcal{A}(\mathcal{E}) = \{(x, y) \in (\prod_{i \in M} X_i) \times Y \mid \sum_{i \in M} x_i = y + \omega\}.$$

In the following, $\mathcal{A}_X(\mathcal{E})$ will denote the projection of $\mathcal{A}(\mathcal{E})$ on $X = \prod_{i \in M} X_i$.

Definition 3.1. $(x^*, y^*) \in \mathcal{A}(\mathcal{E})$ is a *weak Pareto optimal* allocation for the economy \mathcal{E} if there does not exist any $x \in \mathcal{A}_X(\mathcal{E})$ such that $x_i \in P_i(x^*)$ for all $i \in M$.

The concern of this paper is with the decentralization by prices (in a sense to be precised later) of weak locally Pareto optimal allocations whose we give now the precise definition.

Definition 3.2. $(x^*, y^*) \in \mathcal{A}(\mathcal{E})$ is a *weak locally Pareto optimal* allocation for the economy \mathcal{E} if for each $i = 1, \dots, m$, there exists some neighborhood U_i of x_i^* such that there does not exist any $x \in \mathcal{A}_X(\mathcal{E})$ satisfying $x_i \in (P_i(x^*) \cap U_i)$ for all $i \in M$.

The set of weak locally Pareto optimal allocations obviously contains the set of weak Pareto optimal allocations. When individual preferences are strictly quasi-convex, the local notions of optimality coincide with the global ones.

We thus start with a weak locally Pareto optimal allocation (x^*, y^*) and make on \mathcal{E} the following assumptions:

A.1: $\forall i \in M$, $X_i = L_+$, $x_i^* \in \text{cl } P_i(x^*)$ and there exist $\delta_{x_i^*} > 0$, $\lambda_{x_i^*} > 0$ and $\theta_{x_i^*} > 0$ such that

$$L_+ \cap ((P_i(x^*) \cap B(x_i^*, \theta_{x_i^*})) + \Gamma_{x_i^*}) \subset P_i(x^*)$$

where $\Gamma_{x_i^*}$ denotes the set $\Gamma_{x_i^*} := \bigcup_{\lambda \in]0, \lambda_{x_i^*}] } \lambda((1/(m+1))\omega + \delta_{x_i^*} B)$;

A.2: Y is norm-closed and there exist $\delta_{y^*} > 0$, $\lambda_{y^*} > 0$, and $\theta_{y^*} > 0$ such that

$$\forall y \in Y \cap B(y^*, \theta_{y^*}), ((y - \Gamma_{y^*}) \cap \{z \in L \mid z^+ \leq y^+\}) \subset Y$$

where Γ_{y^*} denotes the set $\Gamma_{y^*} := \bigcup_{\lambda \in]0, \lambda_{y^*}] } \lambda((1/(m+1))\omega + \delta_{y^*} B)$.

Remarks 3.3.

- (a) The formulation of $(1/(m+1))\omega$ -properness of preferences in Assumptions A.1 is local and close to the one given by Podczeck [28] in the convex case. It implies that $\omega > 0$ and is implied by the more classical assumption

$$L_+ \cap (P_i(x_i^*) + K_i^*) \subset P_i(x_i^*)$$

where K_i^* is the whole open cone generated by $\Gamma_{x_i^*}$. When preferred sets are derived from a transitive and complete preference relation on consumption sets, properness at some point of the consumption set is implied by uniform properness as formulated by Mas-Colell [22]. To be restricted to consumption sets equal to the positive cone of the commodity space is a counterpart for using properness.

- (b) As proved in Proposition 4.1, local properness at x^* of preferred sets, as stated in A.1, is equivalent to the assumption that each $P_i(x^*)$ is the trace on L_+ of some set, $\widehat{P}_i(x^*)$, epi-Lipschitz at x_i^* with respect to ω :

$$\forall i \in M, P_i(x^*) = \widehat{P}_i(x^*) \cap L_+.$$

In the convex case, Tourky [32] states an analogous condition.

- (c) In A.2, we follow (and weaken) Richard [29] for formulating the local properness of a production set at some point of this set. It is well-known that properness as defined by Richard is weaker than the definition first given by Mas-Colell [23]. Here, the local properness of Y at $y^* \in Y$, as stated in A.2, is implied by the assumption that

$$Y = \widehat{Y}(y^*) \cap Z_{y^*}$$

for some set, $\widehat{Y}(y^*)$, epi-Lipschitz at y^* with respect to $-\omega$, and some closed *pretechnology* sublattice⁷ of L , Z_{y^*} , comprehensive ($Z_{y^*} - L_+ = Z_{y^*}$), containing 0 and such that $Y \subset Z_{y^*}$. In the convex case, Tourky [33] states an analogous condition.

- (d) The free-disposal production set $Y = -L_+$ satisfies A.2, but $Y = \{0\}$ does not satisfies A.2. Hence the assumptions made in this paper do not cover the case of a pure exchange economy without disposal. The supportability by prices of a pure exchange economy will be established as a corollary of the main result of this paper we next present.

Theorem 3.4. *Assume that ∂ is any subdifferential satisfying the properties (a) – (g) and robust for distance functions. Let (x^*, y^*) be a weak locally Pareto optimal allocation of an economy \mathcal{E} satisfying at (x^*, y^*) the assumptions A.1, A.2. There exists a price $p^* \in L^*$ (the topological dual of L), $p^* \neq 0$, such that*

- a) $p^* \in \partial d_Y(y^*)$,
b) $-p^* \in \bigcap_{i \in M} \partial d_{\text{cl}(P_i(x^*))}(x_i^*)$.

Moreover, $p^* \cdot \omega > 0$.

Remark 3.5.

It is not necessary to assume as in A.1 and A.2 that $(1/(m+1))\omega$ is a common properness vector. Replacing $(1/m+1)\omega$ in the definition of $\Gamma_{x_i^*}$, $i \in M$ and Γ_{y^*} respectively by some $v_{x_i^*} > 0$, $i \in M$ and $v_{y^*} > 0$ and rewriting the proof of Claim 4.1 below would allow us to prove the existence of p^* satisfying a) and b) and $p^* \cdot (\sum_{i \in M} v_{x_i^*} + v_{y^*}) > 0$.

In the case of an exchange economy, we state:

Corollary 3.6. *Assume that ∂ is any subdifferential satisfying the properties (a) – (g) and robust for distance functions. Let x^* be a weak locally Pareto optimal allocation of an economy \mathcal{E} satisfying*

⁷A slightly weaker assumption would be Z_{y^*} is a comprehensive subset of L , satisfying for all $z \in Z_{y^*}$, $z^+ \in Z_{y^*}$.

at x^* Assumption A.1. There exists a price $p^* \in L^*$ (the topological dual of L), $p^* \neq 0$, such that $-p^* \in \bigcap_{i \in M} \partial d_{\text{cl}(P_i(x^*))}(x_i^*)$.

Moreover, $p^* \cdot \omega > 0$.

In the convex case, the conclusion of Theorem 3.4 means that for each consumer i , x_i^* minimizes $p^* \cdot x_i$ over $\text{cl}(P_i(x^*))$, while y^* maximizes $p^* \cdot y$ over the total production set Y . In the nonconvex case, a) and b) express the first order conditions for these optimizing behaviours. In the spirit of Debreu's terminology, (x^*, y^*, p^*) will be called a *quasi-valuation equilibrium*.

Remark 3.7.

Recall that weak Pareto optimal allocations exist under several sets of assumptions on \mathcal{E} . For example, if each preference correspondence P_i derives from a complete preorder on X_i then Pareto optimal allocations exist if for some vector space topology σ on L , $\mathcal{A}_X(\mathcal{E})$ is a σ^m -compact subset of $\prod_{i=1}^m X_i$ and the correspondences P_i have σ^m -open fibers in $\prod_{i=1}^m X_i$.⁸ If each preference correspondence P_i is convex-valued then weak Pareto optimal allocations exist under the same conditions, as an immediate consequence of the Browder-Fan theorem. For an exchange economy, and if individual preferences on convex consumption sets can be represented by quasi-concave utility functions, the two previous condition can be replaced by the weaker assumption that either the "utility set" as defined by Mas-Colell in [22] or the "individually rational utility set" is a compact subset of \mathbb{R}^m .⁹ As far we know, a general study of the conditions of existence of weak Pareto optimal allocations in the nonconvex and nontransitive case is missing.

In the application to infinite dimensional economic models, the vector space topology σ on L is generally thought of as the weak topology $\sigma(L, L^*)$ if L is reflexive, the weak-star topology $\sigma(L, M)$ if L has a Banach pre-dual M . The continuity condition put on preference correspondences is then interpreted as an impatience condition. The main difficulty is with the σ^m -compactness of $\mathcal{A}_X(\mathcal{E})$. If L is an ordered Banach space and σ a topology such that order bounded sets are bounded, boundedness of $\mathcal{A}_X(\mathcal{E})$ is often guaranteed by the assumption that consumption sets are bounded from below and the total production set is bounded from above. Note however that if L is a Banach lattice with an order-continuous norm and if consumption sets are equal to L_+ , $\mathcal{A}_X(\mathcal{E})$ is $\sigma(L, L^*)$ -compact if $(Y + \omega) \cap L_+$ is $\sigma(L, L^*)$ -compact (see Theorem 4.2.4 in [1]).

This short survey of literature shows that the domain of application of decentralization results that assume epi-Lipschitzianity of one of the preferred or production sets is the same as for Debreu (54)'s result. It is restricted either to economies defined on an ordered topological vector commodity space whose positive cone has a nonempty interior or to particular examples of economies which have weak locally Pareto optimal allocation without order-boundedness assumptions on consumption and total production sets. As proved in a previous version of this paper (see [11]), the same remark holds for decentralization results which only assume the compactly epi-Lipschitzianity of some preferred or production set at the corresponding component of the allocation, as soon as, in order to guarantee the existence of weak Pareto optimal allocation, the compactly epi-Lipschitz set is also assumed to be bounded from below or bounded from above.

⁸For a proof, see the proof of Theorem 1.5.3 in [1].

⁹When the individually rational utility set is compact, it is proved in [2] that \mathcal{E} has Edgeworth equilibria, thus weak Pareto optimal allocations. For nontransitive but convex valued preferences, a generalization of the Mas-Colell condition can be found in [21].

In counterpart, the main limitation of our results is in the assumption that the commodity space is a Banach lattice. Supporting prices belong to the topological dual of L and it is well-known that such prices may be of difficult economic interpretation if L is not reflexive. A natural application is thus to nonconvex exchange or production economies defined on L_p spaces, $1 < p < \infty$. Extending our results to topological vector commodity spaces which are not topological vector lattices¹⁰ is an objective for future work.

4. PROOFS

4.1. Characterization of properness for individual preferences. For the sake of generality, let us say that a correspondence $P_i: (L_+)^m \rightarrow L_+$ is $v_{x_i^*}$ -proper at $x_i^* \in \text{cl } P_i(x^*)$ with $v_{x_i^*} > 0$ in L as properness vector if there exist $\delta_{x_i^*} > 0$, $\lambda_{x_i^*} > 0$ and $\theta_{x_i^*} > 0$ such that

$$(4.1) \quad L_+ \cap ((P_i(x^*) \cap B(x_i^*, \theta_{x_i^*})) + \Gamma_{x_i^*}) \subset P_i(x^*)$$

where $\Gamma_{x_i^*}$ denotes the set $\Gamma_{x_i^*} := \bigcup_{\lambda \in]0, \lambda_{x_i^*}] } \lambda(v_{x_i^*} + \delta_{x_i^*} B)$.

Proposition 4.1. *The $v_{x_i^*}$ -properness at x_i^* of P_i , as stated above, is equivalent to the assumption that $P_i(x^*)$ is the trace on L_+ of some set, $\widehat{P}_i(x^*)$, epi-Lipschitz at x_i^* with respect to $v_{x_i^*}$, that is:*

$$P_i(x^*) = \widehat{P}_i(x^*) \cap L_+.$$

Proof. It is easy to prove that, as stated above, the $v_{x_i^*}$ -properness at $x_i^* \in \text{cl } P_i(x^*)$ of $P_i(x^*)$ is implied by the fact that $P_i(x^*)$ is the trace on L_+ of some set, $\widehat{P}_i(x^*)$, epi-Lipschitz at x_i^* with respect to $v_{x_i^*}$. Let us assume conversely that P_i is $v_{x_i^*}$ -proper at $x_i^* \in \text{cl } P_i(x^*)$ and let us construct such set $\widehat{P}_i(x^*)$.

We can suppose that $\delta_{x_i^*} \leq \|v_{x_i^*}\|/2$ and that $\theta_{x_i^*} \leq \lambda_{x_i^*} \|v_{x_i^*}\|/2$. In view of this choice, we first claim that one has

$$(4.2) \quad \Gamma_{x_i^*} \cap B(0, \theta_{x_i^*}/2) \subset (1/2)\Gamma_{x_i^*}.$$

Indeed, if $x \in \Gamma_{x_i^*} \cap B(0, \theta_{x_i^*}/2)$, then there exist some $\lambda \in]0, \lambda_{x_i^*}]$ and $u \in B$, such that $x = \lambda(v_{x_i^*} + \delta_{x_i^*} u)$ with

$$\theta_{x_i^*}/2 \geq \|x\| \geq \lambda(\|v_{x_i^*}\| - \delta_{x_i^*}) \geq \lambda(\|v_{x_i^*}\|)/2.$$

Consequently, $\lambda \leq \lambda_{x_i^*}/2$ and $x \in (1/2)\Gamma_{x_i^*}$.

We next define

$$\widehat{P}_i(x^*) = P_i(x^*) \cup ((P_i(x^*) \cap B(x_i^*, \theta_{x_i^*}/4)) + \Gamma_{x_i^*}).$$

In view of (4.1), $\widehat{P}_i(x^*) \cap L_+ \subset P_i(x^*) \subset \widehat{P}_i(x^*) \cap L_+$, and it only remains to prove that $\widehat{P}_i(x^*)$ is epi-Lipschitz at x_i^* with respect to $v_{x_i^*}$. We will prove more precisely that

$$\left(\widehat{P}_i(x^*) \cap B(x_i^*, \theta_{x_i^*}/4) \right) + (1/2)\Gamma_{x_i^*} \subset \widehat{P}_i(x^*).$$

Let $z \in \widehat{P}_i(x^*) \cap B(x_i^*, \theta_{x_i^*}/4)$. If $z \in P_i(x^*)$, by definition of $\widehat{P}_i(x^*)$, the inclusion $z + (1/2)\Gamma_{x_i^*} \subset \widehat{P}_i(x^*)$ is an obvious one. Otherwise, $z \in (P_i(x^*) \cap B(x_i^*, \theta_{x_i^*}/4)) + \Gamma_{x_i^*}$; the point z can be written as $x + \gamma$, where $x \in P_i(x^*) \cap B(x_i^*, \theta_{x_i^*}/4)$ and $\gamma \in \Gamma_{x_i^*}$. Since x and z are in $B(x_i^*, \theta_{x_i^*}/4)$, $\gamma \in B(0, \theta_{x_i^*}/2)$ thus, in view of (4.2), $\gamma \in (1/2)\Gamma_{x_i^*}$, and $x + (1/2)\Gamma_{x_i^*} \subset \widehat{P}_i(x^*)$. \square

¹⁰An example of space of economic interest, used for modelling commodity differentiation, is $(\mathcal{M}(K), \sigma(\mathcal{M}(K), \mathcal{C}(K)))$, the space of signed measures on a compact metric space K endowed with the weak-star topology relative to its predual, the space $\mathcal{C}(K)$ of continuous real functions defined on K .

4.2. Proof of Theorem 3.4. The proof is done in a sequence of claims that we shall establish successively. The first claim and its proof are classical in the literature devoted to properness assumptions.

Let $\delta = \min\{(\delta_{x_i^*})_{i \in M}, \delta_{y^*}\}$. Using the notations of Definition 3.4, it is possible to choose some $\theta > 0$ satisfying for all $i = 1, \dots, m$, $B(x_i^*, 2\theta) \subset U_i$ and $\theta \leq \min\{(\theta_{x_i^*})_{i \in M}, \theta_{y^*}\}$. Moreover, we will choose $\bar{\lambda} > 0$, small enough (in particular smaller than $\min\{(\lambda_{x_i^*})_{i \in M}, \lambda_Y\}$) such that $\Gamma \subset B(0, \theta)$, where Γ is defined by $\Gamma = \bigcup_{\lambda \in]0, \bar{\lambda}[} (\lambda/(m+1))(\omega + \delta B)$.

Claim 4.1. $\omega \notin \sum_{i \in M} ((P_i(x^*) \cap B(x_i^*, \theta)) + \Gamma) - ((Y \cap B(y^*, \theta)) - \Gamma)$.

Proof of Claim 4.1. Otherwise, there exist $x_i \in P_i(x^*) \cap B(x_i^*, \theta)$, $i = 1, \dots, m$, $y \in Y \cap B(y^*, \theta)$, $u \in B$, $\lambda : 0 < \lambda \leq \bar{\lambda}$ such that $\sum_{i \in M} x_i = (1 - \lambda)\omega + \lambda\delta u + y$, which implies

$$\lambda\delta u^+ \leq \sum_{i \in M} (x_i + \lambda(1/(m+1))\omega) + y^- + \lambda(1/(m+1))\omega.$$

Using the decomposition property of vector lattices, we have $\lambda\delta u^+ = \sum_{i \in M} s_i + s_Y$ with for each $i \in M$, $0 \leq s_i \leq x_i + \lambda(1/(m+1))\omega$ and $0 \leq s_Y \leq y^- + \lambda(1/(m+1))\omega$. For each $i \in M$, we let $x'_i = x_i + \lambda(1/(m+1))\omega - s_i$, one has $x'_i \in L_+$ and

$$\sum_{i \in M} x'_i = \omega + y - \lambda(1/(m+1))\omega + (s_Y - \lambda\delta u^-).$$

As $|s_Y - \lambda\delta u^-| \leq s_Y \vee \lambda\delta u^- \leq \lambda\delta u^+ \vee \lambda\delta u^- \leq \lambda\delta|u| \leq \lambda\delta_{y^*}|u|$ and $(y - \lambda(1/(m+1))\omega + (s_Y - \lambda\delta u^-))^+ \leq y^+$, it follows from A.2 that $\sum_{i \in M} x'_i \in \omega + Y$, hence that the consumption allocation $(x'_i)_{i \in M} \in \mathcal{A}_X(\mathcal{E})$. As for each $i \in M$, $0 \leq s_i \leq \lambda\delta u^+ \leq \lambda\delta|u| \leq \lambda\delta_{x_i^*}|u|$ and $x'_i \in L_+$, it follows from A.1 that for each $i \in M$, $x'_i \in P_i(x^*)$. From our choice of $\bar{\lambda}$, for each $i \in M$, $x'_i \in U_i$, which contradicts the weak local Pareto optimality of (x^*, y^*) . \square

Let us now define $\tilde{\Gamma} = (1/2)\Gamma$. The two following claims are devoted to deduce from the first one that $\omega \in \text{bd}(\sum_{i \in M} \text{cl}(P_i(x^*) \cap B(x_i^*, \theta)) - \text{cl}(Y \cap B(y^*, \theta)) + (m+1) \text{cl}\tilde{\Gamma})$.

Claim 4.2. Let $(Q_i)_{i=1}^{m+1}$ be $m+1$ nonempty subsets of L . Then,

$$\text{int} \left(\sum_{i=1}^{m+1} \text{cl} Q_i + (m+1) \text{cl}\tilde{\Gamma} \right) \subset \sum_{i=1}^{m+1} (Q_i + \Gamma).$$

Proof of Claim 4.2. Indeed, let us consider $z \in \text{int}(\sum_{i=1}^{m+1} \text{cl} Q_i + (m+1) \text{cl}\tilde{\Gamma})$. By definition of the interior, for an integer k large enough, $z - (\bar{\lambda}/(2k(m+1)))\omega \in \sum_{i=1}^{m+1} \text{cl} Q_i + (m+1) \text{cl}\tilde{\Gamma}$. By definition of the closure, $\sum_{i=1}^{m+1} \text{cl} Q_i + (m+1) \text{cl}\tilde{\Gamma} \subset \sum_{i=1}^{m+1} Q_i + (m+1)\tilde{\Gamma} + (\bar{\lambda}\delta/(2k(m+1)))B$. These two conditions together with the definition of Γ imply that

$$z \in \sum_{i=1}^{m+1} Q_i + (m+1)\tilde{\Gamma} + \frac{1}{2k} \frac{\bar{\lambda}}{(m+1)} (\omega + \delta B) \subset \sum_{i=1}^{m+1} Q_i + (m+1 + \frac{1}{k})\tilde{\Gamma}.$$

By definition of $\tilde{\Gamma}$, $\sum_{i=1}^{m+1} Q_i + (m+1 + (1/k))\tilde{\Gamma} \subset \sum_{i=1}^{m+1} Q_i + (m+1)\Gamma = \sum_{i=1}^{m+1} (Q_i + \Gamma)$. \square

We will denote by Q_i the set $P_i(x^*) \cap B(x_i^*, \theta)$ ($i = 1, \dots, m$) and by Q_Y the set $-Y \cap B(y^*, \theta)$.

Claim 4.3. $\omega \in \text{bd}(\sum_{i \in M} \text{cl} Q_i + \text{cl} Q_Y + (m+1) \text{cl}\tilde{\Gamma})$.

First, note that it follows from the hypothesis of local nonsatiation of preferences at each x_i^* , contained in A.1, that $\omega \in \sum_{i \in M} \text{cl } Q_i + \text{cl } Q_Y + (m+1) \text{cl } \tilde{\Gamma}$. Claim 4.1 together with Claim 4.2 applied to the sets Q_1, \dots, Q_m, Q_Y lead to $\omega \notin \text{int}(\sum_{i \in M} \text{cl } Q_i + \text{cl } Q_Y + (m+1) \text{cl } \tilde{\Gamma})$ and the conclusion holds. \square

Let now (ε^k) be a sequence of positive real numbers converging to 0. In view of Claim 4.3, we can apply Theorem 2.1 (Theorem 1 of Borwein-Jofré), in order to get for every k some $p^k \in X^*$ such that

$$\begin{aligned} \forall i \in M, \quad -p^k &\in \partial d_{\text{cl } Q_i}(x_i^k) + \varepsilon^k B^*, \\ -p^k &\in \partial d_{-Q_Y}(-y^k) + \varepsilon^k B^*, \\ -p^k &\in \partial d_{\text{cl } \tilde{\Gamma}}(z^k) + \varepsilon^k B^*, \\ 0 < c &\leq \|p^k\| \leq 1 \end{aligned}$$

where $x_i^k \in (x_i^* + \varepsilon^k B)$, $y^k \in (y^* + \varepsilon^k B)$, $z^k \in \varepsilon^k B$ and where c does not depend on k . Letting k tend to infinity and by passing to subnets if necessary, we get $p^k \xrightarrow{\sigma^*(X^*, X)} p^*$. It then follows from the robustness of the subdifferential of the distance function that

$$\forall i \in M, \quad -p^* \in \partial d_{\text{cl } Q_i}(x_i^*), \quad -p^* \in \partial d_{-Q_Y}(-y^*) \quad \text{and} \quad -p^* \in \partial d_{\text{cl } \tilde{\Gamma}}(0).$$

At this stage, it is necessary to prove that $p^* \neq 0$.

Claim 4.4. $p^* \neq 0$.

Proof. Otherwise using the decomposition $p^k = -u^k + v^k$, where $u^k \in \partial d_{\text{cl } \tilde{\Gamma}}(z^k)$ and $v^k \in \varepsilon^k B^*$, one has $u^k \xrightarrow{\sigma^*(X^*, X)} 0$, and we will prove that it implies the norm-convergence of u^k to 0, which contradicts that $\|p^k\| = \|-u^k + v^k\| \geq c > 0$ since $v^k \in \varepsilon^k B^*$. Using condition (c) on the subdifferential, u^k belongs to the classical normal cone of convex analysis at point z^k . This means that for all $z \in \text{cl } \tilde{\Gamma}$,

$$(4.3) \quad u^k \cdot (z - z^k) \leq 0, \quad \text{or} \quad u^k \cdot z \leq u^k \cdot z^k.$$

Let us first remark that $u^k \cdot z^k \rightarrow 0$ since $u^k \in (1 + \varepsilon^k)B^*$ and $z^k \in \varepsilon^k B$. By definition of $\tilde{\Gamma}$, for all $u \in B$, both $(\bar{\lambda}/(2(m+1))(\omega - \delta u))$ and $(\bar{\lambda}/(2(m+1))(\omega + \delta u))$ are in $\text{cl } \tilde{\Gamma}$. For these points, the inequality (4.3) allows to give explicit bounds on $u^k \cdot u$:

$$\frac{1}{\delta} \left(u^k \cdot \omega - \frac{2(m+1)}{\bar{\lambda}} u^k \cdot z^k \right) \leq u^k \cdot u \leq \frac{1}{\delta} \left(\frac{2(m+1)}{\bar{\lambda}} u^k \cdot z^k - u^k \cdot \omega \right).$$

These inequalities together with the $\sigma^*(X^*, X)$ convergence of (u^k) to 0 and our first remark lead to the norm convergence of (u^k) to 0 and the conclusion holds. \square

Note that in view of the definitions of the sets Q_i and Q_Y , it follows that the functions $d_{\text{cl } Q_i}$ and $d_{\text{cl } P_i(x^*)}$ coincide on the ball $B(x_i^*, \theta)$ and consequently using Property (b) of the subdifferential, one gets $-p^* \in \partial d_{\text{cl } P_i(x^*)}(x_i^*)$. Finally, using the properties (b) and (g) of the subdifferential, we get: $p^* \in \partial d_Y(y^*)$. As $p^* \cdot \text{cl } \tilde{\Gamma} \geq 0$, obviously $p^* \cdot \omega > 0$ \square

4.3. Proof of Corollary 3.6. Let δ such that $0 < \delta < \min\{\delta_{x_i^*}\}_{i \in M}\}$. Using the notations of Definition 3.4, it is possible to choose some $\theta > 0$ satisfying for all $i = 1, \dots, m$, $B(x_i^*, 2\theta) \subset U_i$ and $\theta \leq \min\{\theta_{x_i^*}\}_{i \in M}\}$. Moreover, we will choose $\bar{\lambda} > 0$ small enough (in particular smaller than $\min\{\lambda_{x_i^*}\}_{i \in M}\}$) such that $\text{cl}\Gamma \subset B(0, \theta)$, where Γ denotes $\Gamma = \bigcup_{\lambda \in]0, \bar{\lambda}[} \lambda((1/(m+1))\omega + \delta B)$. Note that in view of our condition on δ , one has $\text{cl}\Gamma \subset \Gamma_i^* \cup \{0\}$.

We will construct an auxiliary economy with production, denoted by $\mathcal{E}' = ((X_i, P_i)_{i \in M}, Y', \omega)$ whose production set Y' is equal to $-(\text{cl}\Gamma \cap L_+)$.

We first state and prove Claims 4.5 and 4.6 in order to apply Theorem 3.4 to the allocation $(x^*, 0)$ for the economy \mathcal{E}' .

Claim 4.5. Assumption A.2 is satisfied at point $y^* = 0$.

Proof of claim 4.5. First by construction, the set Y' is closed. We will prove that for all $y \in Y' \cap B(0, \theta)$, if $z \in (y - (1/2)\Gamma) \cap \{z \in L \mid z^+ \leq y^+\}$, then $z \in Y'$.

Since $y \in Y'$, $y^+ = 0$, and consequently $z^+ = 0$, which signifies $z \in -L^+$.

Since $z = y - \gamma$, where $y \in Y' \cap B(0, \theta)$ and $\gamma \in (1/2)\Gamma$, from our choice on θ , it is immediate to check that $y \in (-1/2)\text{cl}\Gamma$ and consequently, $z \in (-1/2)\text{cl}\Gamma - (1/2)\Gamma \subset -\text{cl}\Gamma$. \square

Claim 4.6. The allocation $(x^*, 0)$ is a weak local Pareto optimal allocation of the economy \mathcal{E}' .

Proof of claim 4.6. Indeed, otherwise there exists an allocation $((x_i)_{i \in M}, y) \in \mathcal{A}(\mathcal{E})$ such that for all i , $x_i \in P_i(x^*) \cap B(x_i^*, \theta)$. Letting for all i , $x'_i = x_i - (1/m)y$, recalling that $Y' \subset -L_+$, the points x'_i are obviously in L_+ .

Since $y \in -(\text{cl}\Gamma)$, one deduces that either $y = 0$ or $y \in \Gamma_i^*$. If $y = 0$, then $x'_i = x_i \in P_i(x^*)$, and otherwise since $y \in \Gamma_i^*$, it follows from Assumption A.1 that $x'_i \in P_i(x^*)$.

Finally by construction, one has $x'_i \in B(x_i^*, 2\theta) \subset U_i$ which contradicts the weak local Pareto optimality of (x^*) in the exchange economy. \square

In view of Claims 4.5 and 4.6, one can apply Theorem 3.4 to get the existence of p^* which satisfy the conclusion of Corollary 3.6. \square
