Les cahiers de la série scientifique (CS) visent à rendre accessibles des résultats de recherche effectuée au CIRANO afin de susciter échanges et commentaires. Ces cahiers sont écrits dans le style des publications scientifiques. Les idées et les opinions émises sont sous l'unique responsabilité des auteurs et ne représentent pas nécessairement les positions du CIRANO ou de ses partenaires.

This paper presents research carried out at CIRANO and aims at encouraging discussion and comment. The observations and viewpoints expressed are the sole responsibility of the authors. They do not necessarily represent positions of CIRANO or its partners.

Maximum Likelihood and the Bootstrap for Nonlinear Dynamic Models^{*}

Sílvia Gonçalves[†] and Halbert White[‡]

Résumé / Abstract

Nous proposons une approche unifiée pour analyser la méthode de bootstrap appliquée aux estimateurs de pseudo-maximum de vraisemblance dans le contexte de modèles non linéaires dynamiques où les données sont caractérisées par une dépendance d'époque proche. Nous appliquons nos résultats à la méthode de bootstrap de blocs mouvants de Künsch (1989) et Liu et Singh (1992) et nous démontrons la validité asymptotique de premier ordre de l'approximation du bootstrap à la distribution asymptotique de l'estimateur de pseudo-maximum de vraisemblance. Nous considérons aussi l'application du bootstrap à la réalisation de tests d'hypothèses. En particulier, nous démontrons la validité asymptotique des versions de bootstrap des tests de Wald et du multiplicateur de Lagrange.

We provide a unified framework for analyzing bootstrapped extremum estimators of nonlinear dynamic models for heterogeneous dependent stochastic processes. We apply our results to the moving blocks bootstrap of Künsch (1989) and Liu and Singh (1992) and prove the first order asymptotic validity of the bootstrap approximation to the true distribution of quasi-maximum likelihood estimators. We also consider bootstrap testing. In particular, we prove the first order asymptotic validity of the bootstrap distribution of suitable bootstrap analogs of Wald and Lagrange Multiplier statistics for testing hypotheses.

Mots-Clés : Bootstrap en bloc, pseudo-maximum de vraisemblance, modèle non linéaire dynamique, dépendance d'époque proche, test de Wald.

Keywords: *Block bootstrap, quasi-maximum likelihood estimator, nonlinear dynamic model, near epoch dependence, Wald test.*

^{*} We would like to thank Rui Castro and Nour Meddahi for many helpful discussions, and Jeff Wooldridge for suggesting the logit example. In addition, we are grateful to numerous seminar participants on earlier versions of this paper, and to three anonymous referees and a co-editor for many valuable suggestions.

1. Introduction

The bootstrap is a powerful and increasingly utilized method for obtaining confidence intervals and performing statistical inference. Despite this, results validating the bootstrap for the quasi-maximum likelihood estimator (QMLE) or generalized method of moments (GMM) estimator have previously been available only under restrictive assumptions, such as stationarity and limited memory. A main goal here is thus to establish the bootstrap's first order asymptotic validity in the framework of Gallant and White (1988) and Pötscher and Prucha (1991): extremum estimators for nonlinear dynamic models of stochastic processes near epoch dependent (NED) on an underlying mixing process. We treat primarily QML estimators for concreteness and because there are fewer results in this area. See Corradi and Swanson (2001) for a treatment of GMM estimation that draws on the results provided here.

We apply our results to the moving blocks bootstrap (MBB) of Künsch (1989) and Liu and Singh (1992). Here, this involves resampling blocks of the quasi-log-likelihood values. With misspecified models, the associated scores are generally dependent, justifying our use of block bootstrap methods.

Results for bootstrapping extremum estimators are available for special cases. For example, Hahn (1996) shows first order asymptotic validity of Efron's bootstrap for GMM with i.i.d. data. Hall and Horowitz (1996) give asymptotic refinements for bootstrapped GMM estimators with stationary ergodic data. Andrews (2001) extends their results, establishing higher-order improvements of k -step bootstrap estimators (see Davidson and MacKinnon (1999)) for nonlinear extremum estimators, including GMM and ML. Both Hall and Horowitz (1996) and Andrews (2001) take the moment conditions defining the estimator to be uncorrelated after finitely many lags, obviating use of HAC covariance estimators. For stationary mixing processes, Inoue and Shintani (2001) prove asymptotic refinements for GMM applied to linear models where the defining moment conditions have unknown covariance.

Here, we do not attempt asymptotic refinements. Instead, we prove the consistency of the block bootstrap estimator of the QMLE sampling distribution for a broad class of models and data generating processes. Specifically, we avoid stationarity and restrictive memory conditions, and show that the block bootstrap distribution of the QMLE converges weakly to the distribution of the QMLE. Thus, bootstrap confidence intervals have correct asymptotic coverage probability.

An important bootstrap application is hypothesis testing. We show first order asymptotic validity

for new bootstrap Wald and LM tests. The asymptotic validity of the percentile- t test follows from that of the Wald test, justifying use of MBB to construct percentile- t confidence intervals.

We illustrate MBB finite sample performance for confidence intervals via two Monte Carlo experiments. Specifically, we compute confidence intervals for 1) a logit model with neglected autocorrelation, and 2) a possibly misspecified ARCH(1) model. In both cases the MBB outperforms standard asymptotics, especially when robustness to autocorrelated scores is needed.

2. Consistency of the Bootstrap QMLE

We adopt the framework of Gallant and White (1988) (GW). The goal is to conduct inference on a parameter of interest θ_n^o from data X_{n1}, \dots, X_{nn} near epoch dependent (NED) on an underlying mixing process. Here, X_{nt} is a vector containing both explanatory and dependent variables. We define $\{X_{nt}\}$ to be NED on a mixing process $\{V_t\}$ if $E(X_{nt}^2) < \infty$ and $v_k \equiv \sup_{n,t} \left\| X_{nt} - E_{t-k}^{t+k}(X_{nt}) \right\|_2 \rightarrow 0$ as $k \rightarrow \infty$. Here, $\|X_{nt}\|_p \equiv (E|X_{nt}|^p)^{1/p}$ is the L_p norm and $E_{t-k}^{t+k}(\cdot) \equiv E(\cdot | \mathcal{F}_{t-k}^{t+k})$, where $\mathcal{F}_{t-k}^{t+k} \equiv \sigma(V_{t-k}, \dots, V_{t+k})$ is the σ -field generated by V_{t-k}, \dots, V_{t+k} . If $v_k = O(k^{-a-\delta})$ for some $\delta > 0$, we say $\{X_{nt}\}$ is NED of size $-a$. We assume $\{V_t\}$ is strong mixing; analogous results hold for uniform mixing. The strong mixing coefficients are $\alpha_k \equiv \sup_m \sup_{\{A \in \mathcal{F}_{-\infty}^m, B \in \mathcal{F}_{m+k}^\infty\}} |P(A \cap B) - P(A)P(B)|$; we require $\alpha_k \rightarrow 0$ as $k \rightarrow \infty$ suitably fast.

Our methods involve using the MBB to resample certain functions of the data. Thus, consider a generic array of random variables $\{Z_{nt} : t = 1, \dots, n\}$. Let $\ell = \ell_n \in \mathbb{N}$ ($1 \leq \ell < n$) be a block length, and let $B_{t,\ell} = \{Z_{nt}, Z_{n,t+1}, \dots, Z_{n,t+\ell-1}\}$ be the block of ℓ consecutive observations starting at Z_{nt} ($\ell = 1$ gives the standard bootstrap). For simplicity take $n = k\ell$. The MBB draws $k = n/\ell$ blocks randomly with replacement from the set of overlapping blocks $\{B_{1,\ell}, \dots, B_{n-\ell+1,\ell}\}$. Letting I_{n1}, \dots, I_{nk} be i.i.d. random variables distributed uniformly on $\{0, \dots, n - \ell\}$, we have $\{Z_{nt}^* = Z_{n,\tau_{nt}}, t = 1, \dots, n\}$, where τ_{nt} defines a random array $\{\tau_{nt}\} \equiv \{I_{n1} + 1, \dots, I_{n1} + \ell, \dots, I_{nk+1}, \dots, I_{nk+\ell}\}$.

The QML estimator $\hat{\theta}_n$ solves the problem

$$\max_{\Theta} L_n(\theta), \quad n = 1, 2, \dots,$$

where $L_n(\theta) \equiv n^{-1} \sum_{t=1}^n \log f_{nt}(X_n^t, \theta)$, $X_n^t \equiv (X'_{n1}, \dots, X'_{nt})'$, $t = 1, 2, \dots, n$, and θ belongs to Θ , a compact subset of \mathbb{R}^p , $p \in \mathbb{N}$. Thus, X_n^t contains all explanatory and dependent variables entering f_{nt} ,

the “quasi-likelihood” for observation t . The function L_n is the “quasi-log-likelihood function”. GW study the properties of the QMLE $\hat{\theta}_n$ (consistency and asymptotic normality) under certain regularity assumptions, collected in Appendix A for convenience.

Given the original sample X_{n1}, \dots, X_{nn} , let $\hat{\theta}_n^*$ be a bootstrap version of $\hat{\theta}_n$, solving

$$\max_{\Theta} L_n^*(\theta), \quad n = 1, 2, \dots,$$

where $L_n^*(\theta) \equiv n^{-1} \sum_{t=1}^n \log f_{nt}^*(\theta)$, and for $n = 1, 2, \dots$ and each $\theta \in \Theta$, $\{f_{nt}^*(\theta), t = 1, \dots, n\}$ is given by $f_{nt}^*(\theta) = f_{n, \tau_{nt}}(X_n^{\tau_{nt}}, \theta)$, with τ_{nt} chosen by the MBB. Thus, the bootstrap QMLE resamples the contributions $\log f_{nt}(X_n^t, \theta)$ to $L_n(\theta)$. This is often equivalent to directly resampling the data, for example in linear regression where f_{nt} depends only upon $X_{nt} = (y_{nt}, W_{nt}')'$ (y_{nt} is the dependent variable at time t and W_{nt} is a vector of explanatory variables at time t that may include lagged dependent variables). In this case, resampling blocks of $f_{nt}(X_n^t, \theta)$ is equivalent to resampling blocks of $X_{nt} = (y_{nt}, W_{nt}')'$, the “blocks of blocks bootstrap” (Politis and Romano, 1992). But if f_{nt} depends on the entire past history X_n^t , it may not be possible to define “tuples” of observables on which to apply the MBB. This is the case for GARCH models; for these, bootstrapping the QMLE does not involve directly bootstrapping the data.

We first show that $\hat{\theta}_n^*$ converges in probability to $\hat{\theta}_n$, conditional on all samples with probability tending to one. Conventionally, P^* is the probability measure induced by the MBB. For a bootstrap statistic T_n^* we write $T_n^* \rightarrow 0 \text{ prob} - P^*$, $\text{prob} - P$ if for any $\varepsilon > 0$ and any $\delta > 0$, $\lim_{n \rightarrow \infty} P[P^* [|T_n^*| > \varepsilon] > \delta] = 0$.

Theorem 2.1. *Let Assumption A hold. Then, $\hat{\theta}_n - \theta_n^o \rightarrow 0 \text{ prob} - P$. If also $\ell_n \rightarrow \infty$, and $\ell_n = o(n)$, then $\hat{\theta}_n^* - \hat{\theta}_n \rightarrow 0 \text{ prob} - P^*$, $\text{prob} - P$.*

Thus, $\hat{\theta}_n$ is asymptotically the bootstrap “pseudo-true parameter”. Nevertheless, as Andrews (2001) notes, for given n , the MBB population first-order conditions evaluated at $\hat{\theta}_n$ are not generally zero. That is, $E^* \left[n^{-1} \sum_{t=1}^n s_{nt}^* \left(\hat{\theta}_n \right) \right] \neq 0$, where $\left\{ s_{nt}^* \left(\hat{\theta}_n \right) = \nabla \log f_{n, \tau_{nt}} \left(X_n^{\tau_{nt}}, \hat{\theta}_n \right) \right\}$. To study higher-order properties of the bootstrap, Andrews (2001) therefore recenters the bootstrap objective function to $L_n^*(\theta) - n^{-1} \sum_{t=1}^n E^* \left(s_{nt}^* \left(\hat{\theta}_n \right) \right)' \theta$. As the first-order properties are unaffected, we leave this aside here. (See also Horowitz (1996) for a similar recentering of the criterion function in the GMM context.)

Next we show that the sampling distribution of $\sqrt{n} \left(\hat{\theta}_n - \theta_n^o \right)$ is well-approximated by the distribution

of $\sqrt{n}(\hat{\theta}_n^* - \hat{\theta}_n)$, conditional on X_{n1}, \dots, X_{nn} . For this, we strengthen Assumption A as follows:

Assumption 2.1

2.1.a) $\{s_{nt}(X_n^t, \theta) \equiv \nabla \log f_{nt}(X_n^t, \theta)\}$ is $3r$ -dominated on Θ uniformly in $n, t = 1, 2, \dots, r > 2$.

2.1.b) For some small $\delta > 0$ and some $r > 2$, the elements of $\{s_{nt}(X_n^t, \theta)\}$ are $L_{2+\delta}$ -NED on $\{V_t\}$ of size $-\frac{2(r-1)}{r-2}$ uniformly on (Θ, ρ) ; $\{V_t\}$ is α -mixing with α_k of size $-\frac{(2+\delta)r}{r-2}$.

Assumption 2.2 $n^{-1} \sum_{t=1}^n E(s_{nt}^o) E(s_{nt}^o)' = o(\ell_n^{-1})$, where $\ell_n = o(n)$ and $\ell_n \rightarrow \infty$.

The consistency of the MBB distribution depends crucially on the consistency of the MBB covariance matrix of the scaled average of the MBB-resampled scores $\{s_{nt}^{*o}\}$. With misspecification, $\{s_{nt}^o\}$ is dependent and possibly heterogeneous. Accordingly, Assumption 3.1.b) takes $\{s_{nt}^o\}$ to be $L_{2+\delta}$ -NED on a mixing process (see Andrews (1988)), for small $\delta > 0$. Application of Gonçalves and White (2001) Theorem 2.1 shows the MBB covariance matrix of the scaled average of $\{s_{nt}^{*o}\}$ is consistent under this NED condition for $B_n^o + U_n^o$, where $B_n^o = \text{var}(n^{-1/2} \sum_{t=1}^n s_{nt}^o)$, and $U_n^o = \text{var}^*(n^{-1/2} \sum_{t=1}^n [E(s_{nt}^o)]^*)$, with $\{[E(s_{nt}^o)]^*\}$ a MBB resample of $\{E(s_{nt}^o)\}$. Assumption 2.2 eliminates the bias U_n^o asymptotically, ensuring that $\hat{\theta}_n^*$ converges to a normal with the correct covariance (cf. GW, p. 102).

Theorem 2.2. *Let Assumption A as strengthened by Assumptions 2.1 and 2.2 hold. If $\ell_n \rightarrow \infty$ and $\ell_n = o(n^{1/2})$, then for any $\varepsilon > 0$, $P \left\{ \sup_{x \in \mathbb{R}^p} \left| P^* \left[\sqrt{n}(\hat{\theta}_n^* - \hat{\theta}_n) \leq x \right] - P \left[\sqrt{n}(\hat{\theta}_n - \theta_n^o) \leq x \right] \right| > \varepsilon \right\} \rightarrow 0$.*

Theorem 2.2 justifies using order statistics of the bootstrap distribution to form percentile confidence intervals for θ_n^o with asymptotically correct coverage probabilities. Note that this does *not* justify using the variance of the bootstrap distribution to consistently estimate the QMLE asymptotic variance without further conditions, e.g. that $\left\{ n(\hat{\theta}_n^* - \hat{\theta}_n)(\hat{\theta}_n^* - \hat{\theta}_n)' \right\}$ is uniformly integrable (e.g. Billingsley, 1995, p. 338). This has been sometimes overlooked in the literature. Counterexamples to the consistency of the bootstrap variance of smooth functions of sample means in the i.i.d. context can be found in Ghosh et. al. (1984) and Shao (1992). See also Gonçalves and White (2000).

Bootstrapping the QMLE may be computationally costly as it requires an optimization for each resample. Davidson and MacKinnon (1999) have proposed approximate bootstrap methods based on a few iterations starting from the original QMLE, achieving the same accuracy as the fully-optimized

bootstrap. Let $A_n^*(\hat{\theta}_n) = n^{-1} \sum_{t=1}^n \nabla^2 \log f_{nt}^*(\hat{\theta}_n)$ be the MBB resampled estimated Hessian, and let $\{s_{nt}^*(\hat{\theta}_n)\}$ be the MBB resampled estimated scores. The one-step MBB QMLE is:

$$\hat{\theta}_{1n}^* = \hat{\theta}_n - A_n^*(\hat{\theta}_n)^{-1} n^{-1} \sum_{t=1}^n s_{nt}^*(\hat{\theta}_n).$$

Corollary 2.1. *Let Assumption A as strengthened by Assumptions 2.1 and 2.2 hold. If $\ell_n = o(n^{1/2})$, then for any $\varepsilon > 0$, $P \left[\sup_{x \in \mathbb{R}^p} \left| P^* \left[\sqrt{n} (\hat{\theta}_n^* - \hat{\theta}_n) \leq x \right] - P^* \left[\sqrt{n} (\hat{\theta}_{1n}^* - \hat{\theta}_n) \leq x \right] \right| > \varepsilon \right] \rightarrow 0$.*

Analogous results hold for the multi-step estimators under the same conditions.

3. Hypothesis Testing

The results of Section 2 do not immediately justify testing hypotheses about θ_n^o based on studentized statistics such as t - or Wald statistics. Nevertheless, they are the key to proving the ability of the bootstrap to approximate the distribution of studentized statistics, as we now show.

Let $\{r_n : \Theta \rightarrow \mathbb{R}^q\}$, with $\Theta \subset \mathbb{R}^p$, $q \leq p$, be a sequence of functions that have elements continuously differentiable on Θ uniformly in n such that $\{R_n^o \equiv \nabla' r_n(\theta_n^o)\}$ is $O(1)$ with full row rank q , uniformly in n . The Wald statistic for testing $H_o : \sqrt{n} r_n(\theta_n^o) \rightarrow 0$ is $\mathcal{W}_n = n \hat{r}_n' \left(\hat{R}_n \hat{C}_n \hat{R}_n' \right)^{-1} \hat{r}_n$, where $\hat{r}_n = r_n(\hat{\theta}_n)$, $\hat{R}_n = \nabla' r_n(\hat{\theta}_n)$ and $\hat{C}_n = \hat{A}_n^{-1} \hat{B}_n \hat{A}_n^{-1}$ is consistent for $C_n^o = A_n^{o-1} B_n^o A_n^{o-1}$. In particular, $\hat{A}_n = n^{-1} \sum_{t=1}^n \nabla^2 \log f_{nt} \left(X_n^t, \hat{\theta}_n \right)$ is an estimator of $A_n^o \equiv E \left(n^{-1} \sum_{t=1}^n \nabla^2 \log f_{nt} \left(X_n^t, \theta_n^o \right) \right)$ and \hat{B}_n is such that $\hat{B}_n - B_n^o \xrightarrow{P} 0$. For our context, \hat{B}_n is a kernel-type variance estimator, e.g. a Bartlett (Newey-West, 1987) or a Quadratic Spectral (Andrews, 1991) estimator. For first order properties, we just need \hat{B}_n to be consistent for B_n^o . Our bootstrap Wald statistic is

$$\mathcal{W}_n^* = n (\hat{r}_n^* - \hat{r}_n)' \left(\hat{R}_n^* \hat{C}_n^* \hat{R}_n^{*'} \right)^{-1} (\hat{r}_n^* - \hat{r}_n),$$

where we set $\hat{r}_n^* = r_n(\hat{\theta}_n^*)$, $\hat{R}_n^* = \nabla' r_n(\hat{\theta}_n^*)$ and $\hat{C}_n^* = \hat{A}_n^{*-1} \hat{B}_n^* \hat{A}_n^{*-1}$. Here, $\hat{A}_n^* = n^{-1} \sum_{t=1}^n \nabla^2 \log f_{n,\tau_{nt}} \left(X_n^{\tau_{nt}}, \hat{\theta}_n^* \right)$ and \hat{B}_n^* is

$$(3.1) \quad \hat{B}_n^* = k^{-1} \sum_{i=1}^k \left(\ell^{-1/2} \sum_{t=1}^{\ell} s_{n, I_{ni}+t} \left(X_n^{I_{ni}+t}, \hat{\theta}_n^* \right) \right) \left(\ell^{-1/2} \sum_{t=1}^{\ell} s_{n, I_{ni}+t} \left(X_n^{I_{ni}+t}, \hat{\theta}_n^* \right) \right)'$$

\hat{B}_n^* is the multivariate QMLE analog of the MBB variance estimator of Davison and Hall (1993) and Götze and Künsch (1996). To motivate this, recall that \hat{B}_n^* is the bootstrap analog of \hat{B}_n , which estimates

B_n^o , the covariance of the scaled average of the scores at θ_n^o . Analogously, \hat{B}_n^* estimates the bootstrap covariance of the scaled average of the resampled scores at $\hat{\theta}_n$, i.e. \hat{B}_n^* is an *estimator* of

$$(3.2) \quad \text{var}^* \left(n^{-1/2} \sum_{t=1}^n s_{nt}^* \left(\hat{\theta}_n \right) \right) = \text{var}^* \left(k^{-1/2} \sum_{i=1}^k \left(\ell^{-1/2} \sum_{t=1}^{\ell} s_{n, I_{ni}+t} \left(X_n^{I_{ni}+t}, \hat{\theta}_n \right) \right) \right).$$

Because the block bootstrap means $\ell^{-1} \sum_{t=1}^{\ell} s_{n, I_{ni}+t} \left(X_n^{I_{ni}+t}, \hat{\theta}_n \right)$ are (conditionally) i.i.d., the estimator (3.1) of the (bootstrap population) variance (3.2) is just the sample variance of these means, with $\hat{\theta}_n$ replaced by $\hat{\theta}_n^*$ to mimic the replacement of θ_n^o with $\hat{\theta}_n$ when computing \hat{B}_n . Note that in (3.1) we use the bootstrap optimization first order conditions to set $\bar{s}_n^* \equiv n^{-1} \sum_{t=1}^n s_{nt}^* \left(\hat{\theta}_n^* \right) = 0$.

Götze and Künsch (1996) note that one must carefully choose the studentizing kernel variance estimator. Instead of triangular weights, rectangular or quadratic weights should be used in estimating B_n^o . Further, $\hat{\theta}_n^*$ should be recentered, as in Hall and Horowitz (1996) and Andrews (2001). These considerations do not affect our first order results, but are important in applications.

To analyze the bootstrap Wald statistic \mathcal{W}_n^* we strengthen Assumption 2.2:

Assumption 2.2' $n^{-1} \sum_{t=1}^n |E(s_{nti}^o)|^{2+\delta} = o\left(\ell_n^{-1-\delta/2}\right)$ for $i = 1, \dots, p$.

Theorem 3.1. *Let the assumptions of Theorem 2.2 hold as strengthened by Assumption 2.2'. Then, under H_o , for all $\varepsilon > 0$, if $\ell = o(n^{1/2})$, $P[\sup_{x \in \mathbb{R}^q} |P^*(\mathcal{W}_n^* \leq x) - P(\mathcal{W}_n \leq x)| > \varepsilon] \rightarrow 0$.*

This proves the first order asymptotic equivalence under the null of the bootstrap Wald and the original Wald statistic. Consistency of a bootstrap t -statistic studentized with \hat{C}_n^* follows by almost identical arguments, justifying the construction of MBB percentile- t confidence intervals.

The bootstrap also works for the Lagrange Multiplier (LM) statistic. Using notation analogous to GW, the LM statistic is \mathcal{L}_n and its bootstrap analog is

$$\mathcal{L}_n^* = n \nabla' L_n^* \left(\tilde{\theta}_n^* \right) \tilde{A}_n^{*-1} \tilde{R}_n^{*'} \left(\tilde{R}_n^* \tilde{C}_n^* \tilde{R}_n^{*'} \right)^{-1} \tilde{R}_n^* \tilde{A}_n^{*-1} \nabla L_n^* \left(\tilde{\theta}_n^* \right),$$

where, with $\tilde{\theta}_n^*$ the constrained bootstrap QMLE, $\nabla L_n^* \left(\tilde{\theta}_n^* \right) \equiv n^{-1} \sum_{t=1}^n s_{nt}^* \left(\tilde{\theta}_n^* \right)$, $\tilde{R}_n^* \equiv \nabla' r_n \left(\tilde{\theta}_n^* \right)$, $\tilde{C}_n^* \equiv \tilde{A}_n^{*-1} \tilde{B}_n^* \tilde{A}_n^{*-1}$, and $\tilde{A}_n^* \equiv n^{-1} \sum_{t=1}^n \nabla^2 \log f_{n, \tau_{nt}} \left(X_n^{\tau_{nt}}, \tilde{\theta}_n^* \right)$. Similarly, \tilde{B}_n^* is as in (3.1) using $\tilde{\theta}_n^*$ instead of $\hat{\theta}_n^*$, with $\ell^{1/2} \nabla L_n^* \left(\tilde{\theta}_n^* \right)$ subtracted off each term $\ell^{-1/2} \sum_{t=1}^{\ell} s_{n, I_{ni}+t} \left(X_n^{I_{ni}+t}, \tilde{\theta}_n^* \right)$ because $\nabla L_n^* \left(\tilde{\theta}_n^* \right)$ is not generally zero.

Theorem 3.2. *Let the assumptions of Theorem 2.2 hold as strengthened by Assumption 2.2'. Then, under H_o , for all $\varepsilon > 0$, if $\ell = o(n^{1/2})$, $P[\sup_{x \in \mathbb{R}^q} |P^*(\mathcal{L}_n^* \leq x) - P(\mathcal{L}_n \leq x)| > \varepsilon] \rightarrow 0$.*

4. Monte Carlo Results

This section provides Monte Carlo evidence on the relative finite sample performance of the MBB and the asymptotic normal approximation for confidence intervals. We consider two practical examples of nonlinear models that are typically estimated by QML. The first examines the MBB percentile- t and asymptotic normal coverage probabilities of confidence intervals in the context of logit models with neglected autocorrelation. Next we compare the MBB to asymptotic normal confidence intervals for possibly misspecified ARCH models.

Confidence Intervals for Logit models

Let a dependent variable y_t take the value 0 or 1, whenever the unobserved $y_t^* = W_t' \beta + \varepsilon_t$ is positive or negative, respectively. W_t is a $k \times 1$ vector of explanatory variables and β a vector of parameters. We generate ε_t as AR(1):

$$\varepsilon_t = \rho \varepsilon_{t-1} + \sqrt{1 - \rho^2} v_t$$

with $\text{Prob}(v_t \leq a) = \frac{\exp(a)}{1 + \exp(a)}$ for any $a \in \mathbb{R}$. Thus, the DGP is logit with autocorrelated errors whenever $\rho \neq 0$. We estimate an ordinary logit model by QMLE ignoring the autocorrelation. The QMLE $\hat{\beta}_n$ remains consistent for β and asymptotically normal (cf. Gouriéroux, Monfort and Trognon (1984) for the related probit model). Nevertheless, confidence intervals for β require an HAC covariance estimator using asymptotic normality, or a bootstrap confidence interval (e.g. a MBB with $\ell > 1$).

Asymptotic normal intervals rely on $t_{\hat{\beta}_i} = \frac{\sqrt{n}(\hat{\beta}_{ni} - \beta_i)}{\sqrt{\hat{C}_{ni,i}}}$, where $\hat{C}_n = \hat{A}_n^{-1} \hat{B}_n \hat{A}_n^{-1}$. We consider three choices for \hat{B}_n : the outer product of the gradient (OP), $\hat{B}_n = n^{-1} \sum_{t=1}^n \hat{s}_{nt} \hat{s}_{nt}'$, and two HAC estimators, using either the Bartlett (BT) or the Quadratic Spectral (QS) kernel. The MBB intervals are based on $t_{\hat{\beta}_{ni}^*} = \frac{\sqrt{n}(\hat{\beta}_{ni}^* - \hat{\beta}_{ni})}{\sqrt{\hat{C}_{ni,i}^*}}$, where $\hat{C}_n^* = \hat{A}_n^{*-1} \hat{B}_n^* \hat{A}_n^{*-1}$, with \hat{B}_n^* as in (3.1). The BT, QS, and MBB intervals are robust to neglected autocorrelation, whereas the OP intervals are not.

Choice of the block size/bandwidth is critical. We use Andrews' (1991) procedure to compute a data-driven block length for BT, QS, and MBB, ensuring meaningful comparisons of our methods.

In the experiments, W contains a constant, and either one, two, three, or four random regressors, independently generated as AR(1) with autocorrelation coefficient equal to 0.5. The intercept is always

0, so on average half the y_t 's are 0 and half are 1. The slope parameters are all set to 0.25. For each experiment we let $\rho \in \{0, 0.5, 0.9\}$, and use 10,000 Monte Carlo trials with 999 bootstrap replications. We discarded 27 out of the 10,000 trials due to nonconvergence of the logit routine with $k = 5$, $n = 50$, $\rho = 0.9$. Nonconvergence in the bootstrap resamples occurred on average less than 0.08% per Monte Carlo trial, for all experiments, except when $k = 5$, $n = 50$, $\rho = 0.9$, in which case this rate was 1.07%. When bootstrap optimization failed, we redrew new bootstrap indices. Table 1 reports coverage rates for the first slope parameter.

Table 1. Coverage Rates of Nominal 95% symmetric Percentile- t Intervals: Logit^a

k	n	ρ	OP	BT	QS	MBB	Avg. Band. /Block size

^a10,000 Monte Carlo trials with 999 bootstrap replications each.

The main results are: a) when $\rho = 0$ all methods work well, even for $n = 50$; b) when $\rho \neq 0$ all intervals undercover, but the robust methods (BT, QS and MBB) outperform OP, as expected. The undercoverage is worse the larger is k and the smaller is n (an exception is MBB when $k = 5$, $\rho = 0.9$, perhaps due to the larger rate of non-convergence); c) the MBB always outperforms BT or QS, especially for small n and large k , and d) the average bandwidth/block size is larger for larger ρ and n , as expected.

Confidence Intervals for ARCH models

We assume the following DGP:

$$(4.1) \quad y_t = \bar{\gamma} + \varepsilon_t, \quad \varepsilon_t = v_t h_t^{1/2}, \quad h_t = \bar{\omega} + \bar{\alpha} \varepsilon_{t-1}^2.$$

A bar denotes true parameters and a superscript o denotes pseudo-true parameters throughout. Usually $\{v_t\}$ is assumed i.i.d. Here, we generate v_t as AR(1):

$$(4.2) \quad v_t = \bar{\rho} v_{t-1} + u_t, \quad |\bar{\rho}| < 1, \quad u_t \sim \text{i.i.d. } N(0, \sigma_u^2), \quad \sigma_u^2 = 1 - \bar{\rho}^2.$$

We can write (4.1)-(4.2) as $y_t = \bar{\gamma} + \bar{\rho} h_t^{1/2} h_{t-1}^{-1/2} (y_{t-1} - \bar{\gamma}) + h_t^{1/2} u_t$, with $u_t \sim \text{i.i.d. } N(0, \sigma_u^2)$. For $\bar{\rho} = 0$, this is the usual ARCH(1). For $\bar{\rho} \neq 0$ an extra term appears. Letting $\mathcal{F}^{t-1} = \sigma(\dots y_{t-2}, y_{t-1})$ and using $v_{t-1} = \varepsilon_{t-1}/h_{t-1}^{1/2}$, we have $E(\varepsilon_t | \mathcal{F}^{t-1}) = \bar{\rho} h_t^{1/2} v_{t-1}$ and $E(\varepsilon_t^2 | \mathcal{F}^{t-1}) = h_t (1 - \bar{\rho}^2 + \bar{\rho}^2 v_{t-1}^2)$, so $E(y_t | \mathcal{F}^{t-1}) = \bar{\gamma} + \bar{\rho} h_t^{1/2} h_{t-1}^{-1/2} (y_{t-1} - \bar{\gamma})$ and $\text{var}(y_t | \mathcal{F}^{t-1}) = \sigma_u^2 h_t$. We (mis)specify a Gaussian ARCH(1) model parameterized by $\theta = (\gamma, \omega, \alpha)'$:

$$y_t = \gamma + e_t, \quad e_t | \mathcal{F}^{t-1} \sim N(0, h_t(\theta)), \quad t = 1, \dots, n,$$

with $h_t(\theta) = \omega + \alpha e_{t-1}^2$. The QMLE $\hat{\theta}_n$ maximizes the log-likelihood

$$(4.3) \quad L_n(\theta) = \frac{1}{2n} \sum_{t=1}^n \log f_t(\theta), \quad \text{where } \log f_t(\theta) = - \left(\ln h_t(\theta) + \frac{e_t^2}{h_t(\theta)} \right).$$

The model is correctly specified if and only if $\bar{\rho} = 0$. With misspecification the QMLE is generally inconsistent for $\bar{\theta} = (\bar{\gamma}, \bar{\omega}, \bar{\alpha})$; instead confidence intervals for pseudo-true parameters $\theta^o = (\gamma^o, \omega^o, \alpha^o)$ pertain. We evaluate θ^o by simulation, as the value maximizing the expectation of (4.3), computed using 50,000 simulations. Considering the expected score corresponding to γ , we have

$$(4.4) \quad E(s_{1t}(\bar{\theta}^o)) = E \left(\frac{\alpha^o \varepsilon_{t-1}}{h_t(\theta^o)} - \frac{\varepsilon_t^2}{h_t^2(\theta^o)} (\alpha^o \varepsilon_{t-1}) + \frac{\varepsilon_t}{h_t(\theta^o)} \right) = 0,$$

where $\bar{\theta}^o = (\bar{\gamma}, \omega^o, \alpha^o)'$, $h_t(\bar{\theta}^o) = \omega^o + \alpha^o \varepsilon_{t-1}^2$ and $\varepsilon_t = y_t - \bar{\gamma}$. For suitably symmetric joint distributions of $(\varepsilon_t, \varepsilon_{t-1})$ centered at zero, it is plausible that this expectation equals zero, implying that $\gamma^o = \bar{\gamma}$, despite the misspecification. Proving this conjecture would distract us from our purpose here, but our simulations (with normal errors) always delivered $\gamma^o = \bar{\gamma}$. Accordingly we set $\gamma^o = \bar{\gamma}$ in what follows.

With misspecification, the scores are generally not a martingale difference sequence, justifying the use of robust inference on θ^o . As before, we consider OP, BT, QS and MBB. All but OP are robust to

^a10,000 Monte Carlo trials with 999 bootstrap replications each. Pseudo-true parameters were calculated by 50,000 simulations: for $\bar{\alpha} = 0.5$, $(\omega^o, \alpha^o) = (0.07, 0.798)$ when $\bar{\rho} = 0.5$ and $(\omega^o, \alpha^o) = (0.017, 1.130)$ when $\bar{\rho} = 0.9$; for $\bar{\alpha} = 0.9$, $(\omega^o, \alpha^o) = (0.069, 1.192)$ when $\bar{\rho} = 0.5$ and $(\omega^o, \alpha^o) = (0.015, 1.480)$ when $\bar{\rho} = 0.9$. $\bar{\gamma} = 1.0$ and $\bar{\omega} = 0.1$ were set throughout.

misspecification. The OP interval is valid if the first two conditional moments of y_t are not misspecified.

Data on $\{y_t\}$ were generated by (4.1)-(4.2) with $\bar{\gamma} = 1.0$, $\bar{\omega} = 0.1$ and six combinations of $\bar{\alpha}$ and $\bar{\rho}$ taken from $\bar{\alpha} \in \{0.5, 0.9\}$ and $\bar{\rho} \in \{0.0, 0.5, 0.9\}$. Table 2 contains results. We summarize as follows.

When $\bar{\rho} = 0$ all methods tend to perform well, though the coverage of the BT and QS intervals tends

to slightly understate the true levels for $\bar{\omega}$ and $\bar{\alpha}$. In contrast, the MBB intervals achieve almost correct coverage for $\bar{\theta}$, with slight overstatement for $\bar{\omega}$. When $\bar{\rho} = 0$, the scores are a martingale difference sequence, and this is reflected in the bandwidth/block size parameter. When $\bar{\rho} \neq 0$, major findings are: (i) the OP intervals fail dramatically for $\bar{\gamma}$, exhibiting severe undercoverage which worsens as $\bar{\rho}$ increases; (ii) the coverages of BT and QS for $\bar{\gamma}$ are also well below the 95% nominal level, but we see clear improvement as n increases; (iii) the MBB outperforms the HAC methods; and (iv) the average chosen bandwidth/block size exceeds one, and tends to increase with n , as we expect.

5. Conclusion

The results presented here justify routine use of MBB methods for the QMLE in a general context. Further results in our setting establishing higher order improvements for the MBB (with recentering) are a logical next step and a promising subject for future work.

Appendix A: Assumptions and Proofs for Section 2

Throughout Appendix A, P is the probability measure governing the behavior of the original time series while $P_{n,\omega}^*$ denotes the probability measure induced by the bootstrap. For any bootstrap statistic $T_n^*(\cdot, \omega)$ we write $T_n^*(\cdot, \omega) \rightarrow 0 \text{ prob} - P_{n,\omega}^*, a.s. - P$ if for any $\varepsilon > 0$ there exists $F \in \mathcal{F}$ with $P(F) = 1$ such that for all ω in F , $\lim_{n \rightarrow \infty} P_{n,\omega}^*[\lambda : |T_n^*(\lambda, \omega)| > \varepsilon] = 0$. We write $T_n^*(\cdot, \omega) \rightarrow 0 \text{ prob} - P_{n,\omega}^*, \text{prob} - P$ if for any $\varepsilon > 0$ and for any $\delta > 0$, $\lim_{n \rightarrow \infty} P[\omega : P_{n,\omega}^*[\lambda : |T_n^*(\lambda, \omega)| > \varepsilon] > \delta] = 0$. Using a subsequence argument (e.g. Billingsley, 1995, Theorem 20.5), $T_n^*(\cdot, \omega) \rightarrow 0 \text{ prob} - P_{n,\omega}^*, \text{prob} - P$ is equivalent to having that for any subsequence $\{n'\}$ there exists a further subsequence $\{n''\}$ such that $T_{n''}^*(\cdot, \omega) \rightarrow 0 \text{ prob} - P_{n'',\omega}^*, a.s. - P$. For any distribution D we write $T_n^*(\cdot, \omega) \Rightarrow^{d_{P_{n,\omega}^*}} D \text{ prob} - P$ when for every subsequence there exists a further subsequence for which weak convergence under $P_{n,\omega}^*$ takes place almost surely $-P$.

Assumption A is the doubly indexed counterpart of the regularity conditions used by GW.

Assumption A

A.1: Let (Ω, \mathcal{F}, P) be a complete probability space. The observed data are a realization of a stochastic process $\{X_{nt} : \Omega \rightarrow \mathbb{R}^l, l \in \mathbb{N}, n, t \in \mathbb{N}\}$, with $X_{nt}(\omega) = W_{nt}(\dots, V_{t-1}(\omega), V_t(\omega), V_{t+1}(\omega), \dots)$, $V_t : \Omega \rightarrow \mathbb{R}^v, v \in \mathbb{N}$, and $W_{nt} : \times_{\tau=-\infty}^{\infty} \mathbb{R}^v \rightarrow \mathbb{R}^l$ such that X_{nt} is measurable for all n, t .

A.2: The functions $f_{nt} : \mathbb{R}^l \times \Theta \rightarrow \mathbb{R}^+$ are such that $f_{nt}(\cdot, \theta)$ is measurable for each $\theta \in \Theta$, a compact subset of $\mathbb{R}^p, p \in \mathbb{N}$, and $f_{nt}(X_n^t, \cdot) : \Theta \rightarrow \mathbb{R}^+$ is continuous on Θ *a.s. - P*, $n, t = 1, 2, \dots$.

A.3: (i) θ_n^o is identifiably unique with respect to $E(L_n(X_n^n, \theta))$. (ii) θ_n^o is interior to Θ uniformly in n .

A.5: (i) $\{\log f_{nt}(X_n^t, \theta)\}$ is Lipschitz continuous on Θ , i.e. $|\log f_{nt}(X_n^t, \theta) - \log f_{nt}(X_n^t, \theta^o)| \leq L_{nt} |\theta - \theta^o|$ a.s. - P , $\forall \theta, \theta^o \in \Theta$, where $\sup_n \{n^{-1} \sum_{t=1}^n E(L_{nt})\} = O(1)$. (ii) $\{\nabla^2 \log f_{nt}(X_n^t, \theta)\}$ is Lipschitz continuous on Θ .

A.6: For some $r > 2$: (i) $\{\log f_{nt}(X_n^t, \theta)\}$ is r -dominated on Θ uniformly in n, t , i.e. there exists $D_{nt} : \mathbb{R}^t \rightarrow \mathbb{R}$ such that $|\log f_{nt}(X_n^t, \theta)| \leq D_{nt}$ for all θ in Θ and D_{nt} is measurable such that $\|D_{nt}\|_r \leq \Delta < \infty$ for all n, t . (ii) $\{\nabla \log f_{nt}(X_n^t, \theta)\}$ is r -dominated on Θ uniformly in n, t . (iii) $\{\nabla^2 \log f_{nt}(X_n^t, \theta)\}$ is r -dominated on Θ uniformly in n, t .

A.7: $\{V_t\}$ is an α -mixing sequence of size $-\frac{2r}{r-2}$, with $r > 2$.

A.8: The elements of (i) $\{\log f_{nt}(X_n^t, \theta)\}$ are NED on $\{V_t\}$ of size $-\frac{1}{2}$; (ii) $\{\nabla \log f_{nt}(X_n^t, \theta)\}$ are NED on $\{V_t\}$ of size -1 uniformly on (Θ, ρ) , where ρ is any convenient norm on \mathbb{R}^p , and (iii) $\{\nabla^2 \log f_{nt}(X_n^t, \theta)\}$ are NED on $\{V_t\}$ of size $-\frac{1}{2}$ uniformly on (Θ, ρ) .

A.9: (i) $\left\{B_n^o \equiv \text{var} \left(n^{-\frac{1}{2}} \sum_{t=1}^n \nabla \log f_{nt}(X_n^t, \theta_n^o) \right)\right\}$ is uniformly positive definite.
(ii) $\left\{A_n^o \equiv E \left(n^{-1} \sum_{t=1}^n \nabla^2 \log f_{nt}(X_n^t, \theta_n^o) \right)\right\}$ is uniformly nonsingular.

The usefulness of the following lemmas extends beyond the QMLE as they apply to prove the validity of bootstrap methods for other extremum estimators, such as GMM.

Lemma A.1 (Identifiable uniqueness of $\hat{\theta}_n$). *Let (Ω, \mathcal{F}, P) be a complete probability space and let Θ be a compact subset of \mathbb{R}^p , $p \in \mathbb{N}$. Let $\{Q_n : \Omega \times \Theta \rightarrow \overline{\mathbb{R}}\}$ be a sequence of random functions continuous on Θ a.s. - P , and let $\hat{\theta}_n = \arg \max_{\Theta} Q_n(\cdot, \theta)$ a.s. - P . If $\sup_{\theta \in \Theta} |Q_n(\cdot, \theta) - \overline{Q}_n(\theta)| \rightarrow 0$ a.s.- P and if $\{\overline{Q}_n : \Theta \rightarrow \overline{\mathbb{R}}\}$ has identifiably unique maximizers $\{\theta_n^o\}$ on Θ , then $\{\hat{\theta}_n\}$ is identifiably unique on Θ with respect to $\{Q_n\}$ a.s. - P , i.e. there exists $F \in \mathcal{F}$, $P(F) = 1$, such that given any $\varepsilon > 0$ and some $\delta(\varepsilon) > 0$, for each $\omega \in F$, there exists $N(\omega, \varepsilon) < \infty$ such that*

$$\sup_{n \geq N(\omega, \varepsilon)} \left[\max_{\eta^c(\hat{\theta}_n, \varepsilon)} Q_n(\omega, \theta) - Q_n(\omega, \hat{\theta}_n) \right] \leq -\delta(\varepsilon) < 0,$$

where $\eta_n^c(\hat{\theta}_n, \varepsilon)$ is the compact complement of $\eta(\hat{\theta}_n, \varepsilon) \equiv \{\theta \in \Theta : |\theta - \hat{\theta}_n| < \varepsilon\}$. If instead $\sup_{\theta \in \Theta} |Q_n(\cdot, \theta) - \overline{Q}_n(\theta)| \rightarrow 0$ prob - P then for any subsequence $\{\hat{\theta}_{n'}\}$ of $\{\hat{\theta}_n\}$, there exists a further subsequence $\{\hat{\theta}_{n''}\}$ such that $\{\hat{\theta}_{n''}\}$ is identifiably unique with respect to $\{Q_{n''}\}$ a.s. - P .

Lemma A.2 (Consistency of $\hat{\theta}_n^*$). *Let (Ω, \mathcal{F}, P) be a complete probability space and let Θ be a compact subset of \mathbb{R}^p , $p \in \mathbb{N}$. Let $\{Q_n : \Omega \times \Theta \rightarrow \overline{\mathbb{R}}\}$ be such that (a1) $Q_n(\cdot, \theta) : \Omega \rightarrow \overline{\mathbb{R}}$ is measurable- \mathcal{F} for each $\theta \in \Theta$; (a2) $Q_n(\omega, \cdot) : \Theta \rightarrow \overline{\mathbb{R}}$ is continuous on Θ a.s. - P . Let $\hat{\theta}_n = \arg \max_{\Theta} Q_n(\cdot, \theta)$ a.s. - P be measurable and assume there exists $\{\overline{Q}_n : \Theta \rightarrow \overline{\mathbb{R}}\}$ with identifiably unique maximizers $\{\theta_n^o\}$ such that (a3) $\sup_{\theta \in \Theta} |Q_n(\cdot, \theta) - \overline{Q}_n(\theta)| \rightarrow 0$ prob - P . Then,*

$$(A) \quad \hat{\theta}_n - \theta_n^o \rightarrow 0 \text{ prob} - P.$$

Let (Λ, \mathcal{G}) be a measurable space, and for each $\omega \in \Omega$ and $n \in \mathbb{N}$ let $(\Lambda, \mathcal{G}, P_{n,\omega}^*)$ be a complete probability space. Let $\{Q_n^* : \Lambda \times \Omega \times \Theta \rightarrow \overline{\mathbb{R}}\}$ be such that (b1) $Q_n^*(\cdot, \omega, \theta) : \Lambda \rightarrow \overline{\mathbb{R}}$ is measurable- \mathcal{G} for each (ω, θ) in $\Omega \times \Theta$; (b2) $Q_n^*(\lambda, \omega, \cdot) : \Theta \rightarrow \overline{\mathbb{R}}$ is continuous on Θ a.s. - P (i.e. for all λ and almost all ω). Let $\{\hat{\theta}_n^* : \Lambda \times \Omega \rightarrow \Theta\}$ be such that for each $\omega \in \Omega$, $\hat{\theta}_n^*(\cdot, \omega) : \Lambda \rightarrow \Theta$ is measurable- \mathcal{G} and $\hat{\theta}_n^*(\cdot, \omega) = \arg \max_{\Theta} Q_n^*(\cdot, \omega, \theta)$ a.s. - P . Assume further that (b3) $\sup_{\theta \in \Theta} |Q_n^*(\cdot, \omega, \theta) - Q_n(\omega, \theta)| \rightarrow 0$ prob - $P_{n,\omega}^*$, prob - P . Then,

$$(B) \quad \hat{\theta}_n^*(\cdot, \omega) - \hat{\theta}_n(\omega) \rightarrow 0, \text{ prob} - P_{n,\omega}^*, \text{ prob} - P.$$

Lemma A.3 (Asymptotic Normality of $\hat{\theta}_n^*$). Let (Ω, \mathcal{F}, P) be a complete probability space and let Θ be a compact subset of \mathbb{R}^p , $p \in \mathbb{N}$. Let $\{Q_n : \Omega \times \Theta \rightarrow \overline{\mathbb{R}}\}$ be such that (a1) $Q_n(\cdot, \theta) : \Omega \rightarrow \overline{\mathbb{R}}$ is measurable- \mathcal{F} for each $\theta \in \Theta$; (a2) $Q_n(\omega, \cdot) : \Theta \rightarrow \overline{\mathbb{R}}$ is continuously differentiable of order 2 on Θ a.s. - P . Let $\hat{\theta}_n = \arg \max_{\Theta} Q_n(\cdot, \theta)$ a.s. - P be measurable such that $\hat{\theta}_n - \theta_n^o \rightarrow 0$ prob - P , where $\{\theta_n^o\}$ is interior to Θ uniformly in n . Suppose there exists a nonstochastic sequence of $p \times p$ matrices $\{B_n^o\}$ that is $O(1)$ and uniformly positive definite such that (a3) $B_n^{o-1/2} \sqrt{n} \nabla Q_n(\cdot, \theta_n^o) \Rightarrow N(0, I_p)$. Suppose further that there exists a sequence $\{A_n : \Theta \rightarrow \mathbb{R}^{p \times p}\}$ such that $\{A_n\}$ is continuous on Θ uniformly in n , and (a4) $\sup_{\theta \in \Theta} |\nabla^2 Q_n(\cdot, \theta) - A_n(\theta)| \rightarrow 0$ prob - P , where $\{A_n^o \equiv A_n(\theta_n^o)\}$ is $O(1)$ and uniformly nonsingular. Then

$$(A) \quad B_n^{o-1/2} A_n^o \sqrt{n} (\hat{\theta}_n - \theta_n^o) \Rightarrow N(0, I_p).$$

Let (Λ, \mathcal{G}) be a measurable space, and for each $\omega \in \Omega$ and $n \in \mathbb{N}$, let $(\Lambda, \mathcal{G}, P_{n,\omega}^*)$ be a complete probability space. Let $\{Q_n^* : \Lambda \times \Omega \times \Theta \rightarrow \overline{\mathbb{R}}\}$ be such that (b1) $Q_n^*(\cdot, \omega, \theta) : \Lambda \rightarrow \overline{\mathbb{R}}$ is measurable- \mathcal{G} for each (ω, θ) in $\Omega \times \Theta$; (b2) $Q_n^*(\lambda, \omega, \cdot) : \Theta \rightarrow \overline{\mathbb{R}}$ is continuously differentiable of order 2 on Θ a.s. - P . For each $n = 1, 2, \dots$, let $\hat{\theta}_n^*(\cdot, \omega) = \arg \max_{\Theta} Q_n^*(\cdot, \omega, \theta)$ a.s. - P be measurable such that $\hat{\theta}_n^*(\cdot, \omega) - \hat{\theta}_n(\omega) \rightarrow 0$, prob - $P_{n,\omega}^*$, prob - P . Assume further that (b3) $B_n^{o-1/2} \sqrt{n} \nabla Q_n^*(\cdot, \omega, \hat{\theta}_n(\omega)) \Rightarrow^{d_{P_{n,\omega}^*}} N(0, I_p)$ in prob - P ; (b4) $\sup_{\theta \in \Theta} |\nabla^2 Q_n^*(\cdot, \omega, \theta) - \nabla^2 Q_n(\omega, \theta)| \rightarrow 0$ prob - $P_{n,\omega}^*$, prob - P . Then

$$(B) \quad B_n^{o-1/2} A_n^o \sqrt{n} (\hat{\theta}_n^*(\cdot, \omega) - \hat{\theta}_n(\omega)) \Rightarrow^{d_{P_{n,\omega}^*}} N(0, I_p) \text{ prob} - P.$$

Lemma A.4 (Bootstrap Uniform WLLN). Let $\{q_{nt}^*(\cdot, \omega, \theta)\}$ be a MBB resample of $\{q_{nt}(\omega, \theta)\}$ and assume: (a) For each $\theta \in \Theta \subset \mathbb{R}^p$, Θ a compact set, $n^{-1} \sum_{t=1}^n (q_{nt}^*(\cdot, \omega, \theta) - q_{nt}(\omega, \theta)) \rightarrow 0$, prob - $P_{n,\omega}^*$, prob - P ; and (b) $\forall \theta, \theta^o \in \Theta$, $|q_{nt}(\cdot, \theta) - q_{nt}(\cdot, \theta^o)| \leq L_{nt} |\theta - \theta^o|$ a.s. - P , where $\sup_n \{n^{-1} \sum_{t=1}^n E(L_{nt})\} = O(1)$. Then, if $\ell_n = o(n)$, for any $\delta > 0$ and $\xi > 0$,

$$\lim_{n \rightarrow \infty} P \left[P_{n,\omega}^* \left(\sup_{\theta \in \Theta} n^{-1} \left| \sum_{t=1}^n (q_{nt}^*(\cdot, \omega, \theta) - q_{nt}(\omega, \theta)) \right| > \delta \right) > \xi \right] = 0.$$

Lemma A.5 (Bootstrap Pointwise WLLN). For some $r > 2$, let $\{q_{nt} : \Omega \times \Theta \rightarrow \mathbb{R}\}$ be such that for all n, t , there exists $D_{nt} : \Omega \rightarrow \mathbb{R}$ with $|q_{nt}(\cdot, \theta)| \leq D_{nt}$ for all $\theta \in \Theta$ and $\|D_{nt}\|_r \leq \Delta < \infty$. For each $\theta \in \Theta$ let $\{q_{nt}^*(\cdot, \omega, \theta)\}$ be a MBB resample of $\{q_{nt}(\omega, \theta)\}$. If $\ell_n = o(n)$, then for any $\delta > 0$, $\xi > 0$, and for each $\theta \in \Theta$,

$$\lim_{n \rightarrow \infty} P \left[P_{n, \omega}^* \left(n^{-1} \left| \sum_{t=1}^n (q_{nt}^*(\cdot, \omega, \theta) - q_{nt}(\omega, \theta)) \right| > \delta \right) > \xi \right] = 0.$$

Lemma A.6. Let $\{Q_n : \Omega \times \Theta \rightarrow \mathbb{R}\}$ be a sequence of functions continuous on Θ a.s. $- P$ and let $\{\hat{\theta}_n : \Omega \rightarrow \Theta\}$ be such that $\hat{\theta}_n - \theta_n^o \rightarrow 0$ prob $- P$. Suppose $\sup_{\theta \in \Theta} |Q_n(\cdot, \theta) - \bar{Q}_n(\theta)| \rightarrow 0$ prob $- P$ where $\{\bar{Q}_n : \Theta \rightarrow \mathbb{R}\}$ is continuous on Θ uniformly in n . Then,

$$(A) \quad Q_n \left(\cdot, \hat{\theta}_n(\cdot) \right) - \bar{Q}_n(\theta_n^o) \rightarrow 0 \text{ prob } - P.$$

For each $\omega \in \Omega$, let $(\Lambda, \mathcal{G}, P_{n, \omega}^*)$ be a complete probability space. If $\hat{\theta}_n^*(\cdot, \omega) - \hat{\theta}_n(\omega) \rightarrow 0$ prob $- P_{n, \omega}^*$, prob $- P$ and $\sup_{\theta \in \Theta} |Q_n^*(\cdot, \omega, \theta) - Q_n(\omega, \theta)| \rightarrow 0$ prob $- P_{n, \omega}^*$, prob $- P$, then

$$(B) \quad Q_n^* \left(\cdot, \omega, \hat{\theta}_n^*(\cdot, \omega) \right) - Q_n \left(\omega, \hat{\theta}_n(\omega) \right) \rightarrow 0 \text{ prob } - P_{n, \omega}^*, \text{ prob } - P.$$

Proof of Theorem 2.1. We apply Lemma A.2 with $Q_n(\cdot, \theta) = n^{-1} \sum_{t=1}^n q_{nt}(\cdot, \theta)$ and $Q_n^*(\cdot, \omega, \theta) = n^{-1} \sum_{t=1}^n q_{nt}^*(\cdot, \omega, \theta)$, where $q_{nt}(\cdot, \theta) \equiv \log f_{nt}(X_n^t(\cdot), \theta)$, and $\{q_{nt}^*(\cdot, \omega, \theta)\}$ is the MBB resample. Conditions (a1)-(a3) are readily verified under Assumption A. Assumption A.2. implies (b1) and (b2). To verify (b3) apply Lemmas A.4 and A.5, noting that $\ell_n = o(n)$. ■

Proof of Theorem 2.2. We apply Lemma A.3 with the same choices of $Q_n(\cdot, \theta)$ and $Q_n^*(\cdot, \omega, \theta)$ as in Theorem 2.1. The result follows then by Polya's theorem (e.g. Serfling, 1980, p. 20) since $C_n^o = A_n^{o-1} B_n^o A_n^{o-1}$ is $O(1)$ and the normal distribution is everywhere continuous. (a1)-(a4) can be verified as in Theorem 5.7 of GW. (b1) and (b2) follow from A.2. Lemmas A.4 and A.5 imply (b4) given A.5(ii) and A.6(iii) and the conditions on ℓ_n . Lastly, we verify (b3). We have that (for any n and any ω)

$$n^{-1/2} \sum_{t=1}^n s_{nt}^* \left(\cdot, \omega, \hat{\theta}_n \right) - n^{-1/2} \sum_{t=1}^n s_{nt} \left(\omega, \hat{\theta}_n \right) = \xi_{1n} + \xi_{2n} + \xi_{3n},$$

where $\xi_{1n}(\cdot, \omega) \equiv n^{-1/2} \sum_{t=1}^n (s_{nt}^*(\cdot, \omega, \theta_n^o) - s_{nt}(\omega, \theta_n^o))$; $\xi_{2n}(\omega) \equiv -n^{-1/2} \sum_{t=1}^n (s_{nt}(\omega, \hat{\theta}_n) - s_{nt}(\omega, \theta_n^o))$; and $\xi_{3n}(\cdot, \omega) \equiv n^{-1/2} \sum_{t=1}^n (s_{nt}^*(\cdot, \omega, \hat{\theta}_n) - s_{nt}^*(\cdot, \omega, \theta_n^o))$. It suffices to show that for any subsequence n' there exists a further subsequence n'' such that a.s. $- P$ (i) $B_{n''}^{o-1/2} \xi_{1n''}(\cdot, \omega) \Rightarrow_{P_{n'', \omega}^*} N(0, I_p)$, and (ii) $\xi_{2n''}(\omega) + \xi_{3n''}(\cdot, \omega) \rightarrow 0$ prob $- P_{n'', \omega}^*$. The result then follows by Lemma 4.7 of White (2000), since $n''^{-1} \sum_{t=1}^{n''} s_{n''t}(\omega, \hat{\theta}_{n''}) = 0$ for all n'' sufficiently large, a.s. $- P$, by A.3(ii) and the F.O.C. for $\hat{\theta}_{n''}$. Theorem 2.2 of Gonçalves and White (2001) implies (i) under Assumption A strengthened by 2.1 and 2.2. To prove (ii), let $F \equiv F_1 \cap F_2$, with F_1 the set of ω on which (i) holds, and F_2 the set on which the remaining conditions of Lemma A.3 hold. Note that $P(F) = 1$. For fixed ω in F , two mean value expansions yield

$$\xi_{2n''}(\omega) + \xi_{3n''}(\cdot, \omega) = \zeta_{n''}(\cdot, \omega) \sqrt{n''} \left(\hat{\theta}_{n''}(\omega) - \theta_{n''}^o \right),$$

$\zeta_{n''}(\cdot, \omega) = n''^{-1} \sum_{t=1}^{n''} (\nabla' s_{n''t}^*(\cdot, \omega, \bar{\theta}_{n''}^*) - \nabla' s_{n''t}(\omega, \bar{\theta}_{n''}))$, with $\bar{\theta}_{n''}$ and $\bar{\theta}_{n''}^*$ (possibly different) mean values lying between $\hat{\theta}_{n''}$ and $\theta_{n''}^o$. Lemma A.6 implies $\zeta_{n''}(\cdot, \omega) \rightarrow 0$ *prob* - $P_{n'', \omega}^*$ for all $\omega \in F$, given the uniform convergence of $\{\nabla^2 Q_{n''}^*(\cdot, \omega, \theta) - \nabla^2 Q_{n''}(\omega, \theta)\}$ and $\{\nabla^2 Q_{n''}(\omega, \theta) - A_{n''}(\theta)\}$, and the convergences of $\bar{\theta}_{n''} - \theta_{n''}^o$ and $\bar{\theta}_{n''}^* - \theta_{n''}^o$ to zero. Since $\sqrt{n''} \left(\hat{\theta}_{n''}(\omega) - \theta_{n''}^o \right) = O(1)$ on F , it follows that $\xi_{2n''}(\omega) + \xi_{3n''}(\cdot, \omega) \rightarrow 0$ *prob* - $P_{n'', \omega}^*$ for $\omega \in F$, $P(F) = 1$. ■

Proof of Corollary 2.1. We can show $\sqrt{n} \left(\hat{\theta}_{1n}^* - \hat{\theta}_n \right) - \sqrt{n} \left(\hat{\theta}_n^* - \hat{\theta}_n \right) \rightarrow 0$ *prob* - $P_{n, \omega}^*$, *prob* - P , given the definition of $\hat{\theta}_{1n}^*$ and the fact that $\hat{A}_n^* - \hat{A}_n \rightarrow 0$ *prob* - $P_{n, \omega}^*$, *prob* - P , by Lemma A.6. ■

Proof of Lemma A.1. Let $F \equiv \left\{ \omega : \hat{\theta}_n(\omega) - \theta_n^o \rightarrow 0 \right\} \cap \left\{ \omega : \sup_{\Theta} |Q_n(\omega, \theta) - \bar{Q}_n(\theta)| \rightarrow 0 \right\}$. By Theorem 3.4 of White (1994), $P(F) = 1$. Fix $\varepsilon' > 0$ and ω in F . Then, there exists $N_0(\omega, \varepsilon') < \infty$ such that for all $n > N_0(\omega, \varepsilon')$, $\left| \hat{\theta}_n(\omega) - \theta_n^o \right| < \varepsilon'$. Because $\{\theta_n^o\}$ is identifiably unique on Θ , given $\varepsilon' > 0$ there exists $N_1(\varepsilon') < \infty$ and $\delta'(\varepsilon') > 0$ such that $\sup_{n \geq N_1(\varepsilon')} \left[\max_{\eta^c(\theta_n^o, \varepsilon')} \bar{Q}_n(\theta) - \bar{Q}_n(\theta_n^o) \right] \equiv -\delta'(\varepsilon') < 0$, where $\eta(\theta_n^o, \varepsilon') \equiv \{\theta \in \Theta : |\theta - \theta_n^o| < \varepsilon'\}$. By Corollary 3.8 of White (1994), there exists $N_2(\omega, \delta'(\varepsilon')) < \infty$ such that for all $n > N_2(\omega, \delta'(\varepsilon'))$, $\left| Q_n(\omega, \hat{\theta}_n(\omega)) - \bar{Q}_n(\theta_n^o) \right| < \frac{\delta'(\varepsilon')}{4}$. Also, for all $n > N_2(\omega, \delta'(\varepsilon'))$, $\max_{\eta^c(\theta_n^o, \varepsilon')} Q_n(\omega, \theta) \leq \max_{\eta^c(\theta_n^o, \varepsilon')} \bar{Q}_n(\theta) + \frac{\delta'(\varepsilon')}{4}$. Let $N(\omega, \varepsilon') = \max \{N_0(\omega, \varepsilon'), N_1(\varepsilon'), N_2(\omega, \delta'(\varepsilon'))\}$.

Hence

$$\begin{aligned} \sup_{n \geq N(\omega, \varepsilon')} \left[\max_{\eta^c(\hat{\theta}_n(\omega), 2\varepsilon')} Q_n(\omega, \theta) - Q_n(\omega, \hat{\theta}_n(\omega)) \right] &\leq \sup_{n \geq N(\omega, \varepsilon')} \left[\max_{\eta^c(\theta_n^o, \varepsilon')} Q_n(\omega, \theta) - \bar{Q}_n(\theta_n^o) + \frac{\delta'(\varepsilon')}{4} \right] \\ &\leq \sup_{n \geq N(\omega, \varepsilon')} \left[\max_{\eta^c(\theta_n^o, \varepsilon')} \bar{Q}_n(\theta) - \bar{Q}_n(\theta_n^o) + \frac{2\delta'(\varepsilon')}{4} \right] \leq -\frac{\delta'(\varepsilon')}{2}. \end{aligned}$$

Set $\varepsilon = 2\varepsilon'$ and $\delta(\varepsilon) = \frac{\delta'(\varepsilon/2)}{2} > 0$ to obtain the result for all ω in F and $P(F) = 1$. If instead $\sup_{\Theta} |Q_n(\omega, \theta) - \bar{Q}_n(\theta)| \rightarrow 0$ *prob* - P , then for any $\{n'\}$ there exists $\{n''\}$ such that $\sup_{\Theta} |Q_{n''}(\omega, \theta) - \bar{Q}_{n''}(\theta)| = o(1)$ and $\hat{\theta}_{n''}(\omega) - \theta_{n''}^o = o(1)$ *a.s.* - P . The result thus holds for $\{n''\}$ *a.s.* - P . ■

Proof of Lemma A.2. (A) follows by Theorem 3.4 of White (1994) under (a1)-(a3). To prove (B), note that for any subsequence $\{n'\}$, by Lemma A.1 there exists $\{n''\}$ such that $\{\hat{\theta}_{n''}\}$ is identifiably unique *a.s.* - P , given (a1)-(a3). Now apply Theorem 3.4 of White (1994). ■

Proof of Lemma A.3. (A) follows by White's (1994) Theorem 6.2 under (a1)-(a4). To prove (B), it suffices to show that for any subsequence $\{n'\}$ there exists a further subsequence $\{n''\}$ such that $B_{n''}^{*-1/2} A_{n''}^* \sqrt{n''} \left(\hat{\theta}_{n''}^*(\cdot, \omega) - \hat{\theta}_{n''}(\omega) \right) \Rightarrow_{d_{P_{n'', \omega}^*}} N(0, I_p)$, *a.s.* - P . This follows by applying White's (1994) Theorem 6.2 to an appropriately chosen subsequence, given ω in \mathfrak{F} such that $P(\mathfrak{F}) = 1$. ■

Proof of Lemma A.4. The proof closely follows that of Lemma 8 of Hall and Horowitz (1996).

Proof of Lemma A.5. Fix $\theta \in \Theta$, and write $n^{-1} \sum_{t=1}^n (q_{nt}^*(\theta) - q_{nt}(\theta)) = Q_{1n} + Q_{2n}$, with

$$Q_{1n} \equiv n^{-1} \sum_{t=1}^n (q_{nt}^*(\theta) - E^*(q_{nt}^*(\theta))), \text{ and } Q_{2n} \equiv E^* \left(n^{-1} \sum_{t=1}^n q_{nt}^*(\theta) \right) - n^{-1} \sum_{t=1}^n q_{nt}(\theta),$$

where we omit ω to conserve space. $Q_{2n} \rightarrow 0$ *prob - P* since $E^* \left(n^{-1} \sum_{t=1}^n q_{nt}^*(\theta) \right) = n^{-1} \sum_{t=1}^n q_{nt}(\theta) + O_P \left(\frac{\ell}{n} \right)$ (cf. Lemma A.1 of Fitzenberger (1997)) and $\frac{\ell}{n} \rightarrow 0$. By Chebyshev's inequality, for any $\delta > 0$, $P_{n,\omega}^* (|Q_{1n}| > \delta) \leq \frac{1}{\delta^2} n^{-1} \text{var}^* \left(n^{-1/2} \sum_{t=1}^n q_{nt}^*(\theta) \right)$, where $\text{var}^* \left(n^{-1/2} \sum_{t=1}^n q_{nt}^*(\theta) \right)$ has a closed form expression involving products of $q_{nt}(\theta)$ and $q_{n,t+\tau}(\theta)$ (cf. Gonçalves and White (2001)). Under the domination condition on $\{q_{nt}(\theta)\}$ and the properties of the MBB, repeated application of Minkowski and Hölder's inequalities yields $\left\| \text{var}^* \left(n^{-1/2} \sum_{t=1}^n q_{nt}^*(\theta) \right) \right\|_{\frac{r}{2}} = O(\ell)$ for some $r > 2$. Thus, by Markov's inequality, $P \left[P_{n,\omega}^* (|Q_{1n}| > \delta) > \xi \right] = O \left(\left(\frac{\ell}{n} \right)^{r/2} \right) \rightarrow 0$ given $\ell = o(n)$. ■

Proof of Lemma A.6. (A) holds by White (1994, Corollary 3.8). (B) By uniform continuity of \bar{Q}_n on Θ , given $\varepsilon > 0$ there exists $\delta(\varepsilon) > 0$ such that $|\bar{Q}_n(\theta) - \bar{Q}_n(\hat{\theta}_n)| > \varepsilon/3$ implies $|\theta - \hat{\theta}_n| > \delta(\varepsilon)$. So $P \left[P_{n,\omega}^* \left(\left| Q_n^*(\cdot, \omega, \hat{\theta}_n^*) - Q_n(\omega, \hat{\theta}_n) \right| > \varepsilon \right) > \varepsilon \right] \leq P \left[P_{n,\omega}^* \left(\sup_{\Theta} |Q_n^*(\cdot, \omega, \theta) - Q_n(\omega, \theta)| > \varepsilon/3 \right) > \varepsilon/3 \right] + P \left[P_{n,\omega}^* \left(2 \sup_{\Theta} |Q_n(\omega, \theta) - \bar{Q}_n(\theta)| > \varepsilon/3 \right) > \varepsilon/3 \right] + P \left[P_{n,\omega}^* \left(\left| \hat{\theta}_n^* - \hat{\theta}_n \right| > \delta(\varepsilon) \right) > \varepsilon/3 \right] \equiv \xi_1 + \xi_2 + \xi_3$, with obvious definitions. By uniform convergence of $Q_n^*(\cdot, \omega, \theta) - Q_n(\omega, \theta)$ to zero, $\xi_1 \rightarrow 0$. Similarly, by uniform convergence of $Q_n(\cdot, \theta) - \bar{Q}_n(\theta)$ to zero, $\xi_2 \rightarrow 0$ since $\xi_2 \leq P \left(2 \sup_{\Theta} |Q_n(\omega, \theta) - \bar{Q}_n(\theta)| > \varepsilon/3 \right)$. Finally, $\xi_3 \rightarrow 0$ because $\hat{\theta}_n^*(\cdot, \omega) - \hat{\theta}_n(\omega) \rightarrow 0$ *prob - P*, *prob - P*. ■

Appendix B: Proofs for Section 3

Throughout Appendix B, C denotes a generic constant. The dependence of the bootstrap variables on ω and on n will also be omitted as it is not relevant for the arguments made here.

Lemma B.1 (Studentization of the sample mean). *Let $\{X_{nt}\}$ satisfy Assumptions 2.1' and 2.2 of Gonçalves and White (2001), where Assumption 2.2' is strengthened by*

A.2.2' $n^{-1} \sum_{t=1}^n |\mu_{nt} - \bar{\mu}_n|^{2+\delta} = o \left(\ell_n^{-1-\delta/2} \right)$ for some δ such that $0 < \delta \leq 2$.

Then, if $\ell_n \rightarrow \infty$ with $\ell_n = o(n^{1/2})$ we have that for any $\varepsilon > 0$, $\lim_{n \rightarrow \infty} P \left(P^ \left(|\hat{\sigma}_n^{*2} - \hat{\sigma}_n^2| > \varepsilon \right) > \varepsilon \right) = 0$, where $\hat{\sigma}_n^2 = \text{var}^* \left(\sqrt{n} \bar{X}_n^* \right)$ and $\hat{\sigma}_n^{*2} = k^{-1} \sum_{i=1}^k \left(\ell^{-1/2} \sum_{t=1}^{\ell} (X_{I_i+t} - \bar{X}_n^*) \right)^2$.*

Lemma B.2. *Let $\{X_{nt}\}$ and $\{Z_{nt}\}$ satisfy $\|X_{nt}\|_{2+\delta} \leq \Delta$ and $\|Z_{nt}\|_{2+\delta} \leq \Delta$, $t = 1, \dots, n$, $n = 1, 2, \dots$, for any $0 < \delta \leq 2$ and some $\Delta < \infty$. Let $k = n/\ell$. If $\{I_i\}_{i=1}^k$ are i.i.d. uniform on $\{0, \dots, n - \ell\}$ and if $\ell_n \rightarrow \infty$ and $\ell_n = o(n^{1/2})$, then for any $\varepsilon > 0$,*

$$\lim_{n \rightarrow \infty} P \left(P^* \left(\left| k^{-1} \sum_{i=1}^k \ell^{-1} \sum_{t=1}^{\ell} X_{n, I_i+t} \sum_{t=1}^{\ell} Z_{n, I_i+t} \right| > n^{1/2} \varepsilon \right) > \varepsilon \right) = 0.$$

Proof of Theorem 3.1. By GW's Theorem 7.5 $\mathcal{W}_n \Rightarrow \mathcal{X}_q^2$ under H_o . Next, we prove $\mathcal{W}_n^* \Rightarrow^{d_{P^*}} \mathcal{X}_q^2$ *prob - P*. A mean value expansion of $r_n(\hat{\theta}_n^*)$ around $\hat{\theta}_n$ yields $\sqrt{n}(r_n(\hat{\theta}_n^*) - r_n(\hat{\theta}_n)) \Rightarrow^{d_{P^*}} N(0, R_n^o C_n^o R_n^{o'})$ *prob - P*, implying $n(\hat{r}_n^* - \hat{r}_n)'(R_n^o C_n^o R_n^{o'})^{-1}(\hat{r}_n^* - \hat{r}_n) \Rightarrow^{d_{P^*}} \mathcal{X}_q^2$ *prob - P*. Thus, it suffices to prove: (i) $\hat{R}_n^* - R_n^o \rightarrow 0$ *prob - P^*, prob - P*; (ii) $\hat{A}_n^* - A_n^o \rightarrow 0$ *prob - P^*, prob - P*; and (iii) $\hat{B}_n^* - B_n^o \rightarrow 0$ *prob - P^*, prob - P*. (i) follows by continuity of r_n on Θ (uniformly in n) and because $\hat{\theta}_n^* - \theta_n^o \rightarrow 0$ *prob - P^*, prob - P* by Theorem 2.1; similarly, by Theorem 2.1 and Lemma A.6, we have $\hat{A}_n^* - \hat{A}_n \rightarrow 0$ *prob - P^*, prob - P*, which implies (ii) since $\hat{A}_n - A_n^o \rightarrow 0$ *prob - P*. To prove (iii), consider

$$(B.1) \quad \begin{aligned} \tilde{B}_n^{*o} &= k^{-1} \sum_{i=1}^k \left(\ell^{-1/2} \sum_{t=1}^{\ell} (s_{n, I_i+t}(X_n^{I_i+t}, \theta_n^o) - \bar{s}_n^{*o}) \right) \left(\ell^{-1/2} \sum_{t=1}^{\ell} (s_{n, I_i+t}(X_n^{I_i+t}, \theta_n^o) - \bar{s}_n^{*o}) \right)' \\ &= k^{-1} \sum_{i=1}^k \ell^{-1} \sum_{t=1}^{\ell} s_{n, I_i+t}(X_n^{I_i+t}, \theta_n^o) \sum_{t=1}^{\ell} s'_{n, I_i+t}(X_n^{I_i+t}, \theta_n^o) - \ell \bar{s}_n^{*o} \bar{s}_n^{*o'}, \end{aligned}$$

where $\bar{s}_n^{*o} = n^{-1} \sum_{t=1}^n s_{nt}^*(\theta_n^o)$. By Lemma B.1 $\tilde{B}_n^{*o} - B_{n,1}^o \rightarrow 0$, *prob - P^*, prob - P*, where $B_{n,1}^o = \text{var}^*(n^{-1/2} \sum_{t=1}^n s_{nt}^*(\theta_n^o))$. By Gonçalves and White's (2001) Corollary 2.1, $B_{n,1}^o - B_n^o \rightarrow 0$, *prob - P*, implying $\tilde{B}_n^{*o} - B_n^o \rightarrow 0$, *prob - P^*, prob - P*. Thus, it suffices that $\hat{B}_n^* - \tilde{B}_n^{*o} \rightarrow 0$, *prob - P^*, prob - P*.

From (3.1) and (B.1) we can write $\hat{B}_n^* - \tilde{B}_n^{*o} = D_1 + D_2$, where

$$\begin{aligned} D_1 &\equiv k^{-1} \sum_{i=1}^k \ell^{-1} \left[\sum_{t=1}^{\ell} s_{n, I_i+t}(X_n^{I_i+t}, \hat{\theta}_n^*) \sum_{t=1}^{\ell} s'_{n, I_i+t}(X_n^{I_i+t}, \hat{\theta}_n^*) \right. \\ &\quad \left. - \sum_{t=1}^{\ell} s_{n, I_i+t}(X_n^{I_i+t}, \theta_n^o) \sum_{t=1}^{\ell} s'_{n, I_i+t}(X_n^{I_i+t}, \theta_n^o) \right] \end{aligned}$$

and $D_2 \equiv \ell \bar{s}_n^{*o} \bar{s}_n^{*o'}$. Note that $\bar{s}_n^{*o} = B_n^{o1/2} B_n^{o-1/2} (\bar{s}_n^{*o} - \bar{s}_n^o) + B_n^{o1/2} B_n^{o-1/2} \bar{s}_n^o \equiv E_1 + E_2$, with $\bar{s}_n^o = n^{-1} \sum_{t=1}^n s_{nt}^o$. We have $E_1 = O_{P^*}(n^{-1/2})$ *prob - P* by Gonçalves and White's (2001) Theorem 2.2, and $E_2 = O_P(n^{-1/2})$ by the CLT for $\{s_{nt}^o\}$. Thus, $D_2 \rightarrow 0$ *prob - P^*, prob - P*. To show that $D_1 \rightarrow 0$ *prob - P^*, prob - P* we take a mean value expansion about θ_n^o of a typical element of D_1 and apply Lemma B.2 twice with $X_{nt} = \sup_{\theta \in \Theta} \left| \frac{\partial}{\partial \theta'} s_{nt, j}(X_n^t, \theta) \right|$ and $Z_{nt} = \sup_{\theta \in \Theta} |s_{nt, j}(X_n^t, \theta)|$. ■

Proof of Theorem 3.2. The proof follows GW (Theorem 7.9, p. 128) using Lemmas B.1 and B.2.

Proof of Lemma B.1. The proof consists of two steps: (1) show $\tilde{\sigma}_n^{*2} - \hat{\sigma}_n^2 \rightarrow 0$ *prob - P^*, prob - P*, where $\tilde{\sigma}_n^{*2} = k^{-1} \sum_{i=1}^k \left(\ell^{-1/2} \sum_{t=1}^{\ell} (X_{I_i+t} - \bar{X}_{\alpha, n}) \right)^2$, with $\bar{X}_{\alpha, n} = E^*(\bar{X}_n^*)$; (2) show $\hat{\sigma}_n^{*2} - \tilde{\sigma}_n^{*2} \rightarrow 0$ *prob - P^*, prob - P*. Let $\hat{A}_i = \ell^{-1/2} \sum_{t=1}^{\ell} (X_{i+t} - \bar{X}_n^*)$ and $A_i = \ell^{-1/2} \sum_{t=1}^{\ell} (X_{i+t} - \bar{X}_{\alpha, n})$ so that $\hat{\sigma}_n^{*2} = k^{-1} \sum_{i=1}^k \hat{A}_i^2$ and $\tilde{\sigma}_n^{*2} = k^{-1} \sum_{i=1}^k A_i^2$. (1) By two applications of Markov's inequality it suffices to show $E(E^* |\tilde{\sigma}_n^{*2} - \hat{\sigma}_n^{*2}|^p) = o(1)$ for some $p > 1$. We take $p = 1 + \delta/2$ with $0 < \delta \leq 2$. Since $E^*(\tilde{\sigma}_n^{*2}) = E^*(A_{I_1}^2) = (n - \ell + 1)^{-1} \sum_{i=0}^{n-\ell} A_i^2 \equiv \hat{\sigma}_n^2$ (cf. Künsch (1989, Theorems 3.1 and 3.4)), we have

$$E^* |\tilde{\sigma}_n^{*2} - \hat{\sigma}_n^2|^p = E^* \left| k^{-1} \sum_{i=1}^k (A_{I_i}^2 - E^*(A_{I_1}^2)) \right|^p \leq k^{-p} C E^* \left| \sum_{i=1}^k (A_{I_i}^2 - E^*(A_{I_1}^2)) \right|^{p/2},$$

by Burkholder's inequality, because $\{A_{I_i}^2 - E^*(A_{I_i}^2)\}$ are (conditionally) i.i.d. zero mean. For $1 < p \leq 2$, $x \geq 0$ and $y \geq 0$, the inequality $(x + y)^{p/2} \leq x^{p/2} + y^{p/2}$ implies $E^* \left| \sum_{i=1}^k (A_{I_i}^2 - E^*(A_{I_i}^2)) \right|^{p/2} \leq k E^* |A_{I_1}^2 - E^*(A_{I_1}^2)|^p$ so that $E^* |\hat{\sigma}_n^{*2} - \bar{\sigma}_n^2|^p \leq 2^p C k^{-(p-1)} E^* |A_{I_1}|^{2p}$. Thus, it suffices that $k^{-(p-1)} E \left(E^* |A_{I_1}|^{2p} \right) = o(1)$. Some algebra yields $E \left(E^* |A_{I_1}|^{2p} \right) \leq C (F_1 + F_2 + F_3)$, where

$$F_1 = (n - \ell + 1)^{-1} \sum_{i=0}^{n-\ell} \ell^{-p} E \left(\left| \sum_{t=1}^{\ell} Z_{n,i+t} \right|^{2p} \right); F_2 = (n - \ell + 1)^{-1} \sum_{i=0}^{n-\ell} \ell^{-p} \left| \sum_{t=1}^{\ell} (\mu_{n,i+t} - \bar{\mu}_{\alpha,n}) \right|^{2p},$$

and $F_3 = (n - \ell + 1)^{-1} \sum_{i=0}^{n-\ell} \ell^{-p} E \left(\left| \ell \bar{Z}_{\alpha,n} \right|^{2p} \right)$, with $Z_{nt} \equiv X_{nt} - \mu_{nt}$, and for any $\{\mathcal{Y}_{nt}\}$ $\bar{\mathcal{Y}}_{\alpha,n} = (n - \ell + 1)^{-1} \sum_{i=0}^{n-\ell} \ell^{-1} \sum_{t=1}^{\ell} \mathcal{Y}_{n,i+t} = \sum_{t=1}^{\ell} \alpha_{nt} \mathcal{Y}_{nt}$ with $\alpha_{nt} = \frac{1}{(n-\ell+1)\ell} \min\{t, \ell, n-t+1\}$. Under Assumption 2.1', $E \left| \sum_{t=1}^{\ell} Z_{n,i+t} \right|^{2p} < C \ell^p$ (cf. Gonçalves and White (2001), p.18 for a similar argument), implying $k^{-(p-1)} F_1 = O \left(\left(\frac{\ell}{n} \right)^{p-1} \right) = o(1)$, and similarly for $k^{-(p-1)} F_3$. If $\mu_{nt} = \mu$ for all t , $F_2 = 0$ because $\bar{\mu}_{\alpha,n} = \sum_{t=1}^{\ell} \alpha_{nt} \mu = \mu$ as $\sum_{t=1}^{\ell} \alpha_{nt} = 1$. Otherwise, by A.2.2', $F_2 = o(1)$, so $k^{-(p-1)} F_2 = o(1)$. For (2), note $\hat{A}_{I_i} = \sqrt{\ell} (\bar{X}_{I_i} - \bar{X}_n^*)$, where $\bar{X}_{I_i} = \ell^{-1} \sum_{t=1}^{\ell} X_{I_i+t}$, and $A_i = \sqrt{\ell} (\bar{X}_{I_i} - \bar{X}_{\alpha,n})$, implying $\hat{\sigma}_n^{*2} - \bar{\sigma}_n^2 = -\ell (\bar{X}_n^* - \bar{X}_{\alpha,n})^2 = O_{P^*} \left(\frac{\ell}{n} \right) \rightarrow 0$ *prob - P*, since $\sqrt{n} (\bar{X}_n^* - \bar{X}_{\alpha,n}) \Rightarrow^{d_{P^*}} N(0, 1)$ *prob - P* by Theorem 2.2 of Gonçalves and White (2001). ■

Proof of Lemma B.2. Let $S_{n,i}^1 = \sum_{t=1}^{\ell} X_{n,i+t}$ and $S_{n,i}^2 = \sum_{t=1}^{\ell} Z_{n,i+t}$. By Markov's inequality, for some $1 < p \leq 2$, it suffices to show $n^{-p/2} E^* \left(\left| k^{-1} \sum_{i=1}^k \ell^{-1} S_{n,i}^1 S_{n,i}^2 \right|^p \right) \rightarrow 0$ *prob - P*. Let $p = 1 + \delta/2$, $0 < \delta \leq 2$, and note $E^* \left(\left| k^{-1} \sum_{i=1}^k \ell^{-1} S_{n,i}^1 S_{n,i}^2 \right|^p \right) \leq C (F_1 + F_2)$, with

$$F_1 = E^* \left(\left| k^{-1} \sum_{i=1}^k \ell^{-1} (S_{n,i}^1 S_{n,i}^2 - E^*(S_{n,i}^1 S_{n,i}^2)) \right|^p \right) \text{ and } F_2 = E^* \left| k^{-1} \sum_{i=1}^k \ell^{-1} E^*(S_{n,i}^1 S_{n,i}^2) \right|^p.$$

By the Burkholder and c_r -inequalities $F_1 \leq C \ell^{-p} k^{-(p-1)} E^* \left| S_{n,I_1}^1 S_{n,I_1}^2 \right|^p \leq C \ell^{-p} E^* \left| S_{n,I_1}^1 S_{n,I_1}^2 \right|^p$, since $\{S_{n,I_i}^1 S_{n,I_i}^2 - E^*(S_{n,I_i}^1 S_{n,I_i}^2)\}$ are i.i.d. zero mean, and $k^{-(p-1)} \leq 1$ for $p > 1$. Similarly, $F_2 \leq C \ell^{-p} E^* \left| S_{n,I_1}^1 S_{n,I_1}^2 \right|^p$. By the Cauchy-Schwarz and Minkowski inequalities, $E \left(E^* \left| S_{n,I_1}^1 S_{n,I_1}^2 \right|^p \right) \leq C \ell^{2p}$. Thus, $F_1 + F_2 = O_P(\ell^p)$, and so $n^{-p/2} (F_1 + F_2)_P = O \left(\left(\frac{\ell}{n^{1/2}} \right)^p \right) = o_p(1)$, since $\ell = o(n^{1/2})$. ■
