Published online January 28, 2016 in Wiley Online Library (wileyonlinelibrary.com)

Systematic approaches for the design of mixtures, based on a computer-aided mixture/blend design (CAMbD) framework, have the potential to deliver better products and processes. In most existing methodologies the number of mixture ingredients is fixed (usually a binary mixture) and the identity of at least one compound is chosen from a given set of candidate molecules. A novel CAMbD methodology is presented for formulating the general mixture design problem where the number, identity and composition of mixture constituents are optimized simultaneously. To this end, generalized disjunctive programming is integrated into the CAMbD framework to formulate the discrete choices. This generic methodology is applied to a case study to find an optimal solvent mixture that maximizes the solubility of ibuprofen. The best performance in this case study is obtained with a solvent mixture, showing the benefit of using mixtures instead of pure solvents to attain enhanced behavior. © 2016 The Authors AIChE Journal published by Wiley Periodicals, Inc. on behalf of American Institute of Chemical Engineers AIChE J, 62: 1616–1633, 2016

Introduction

Mixtures play an important role in the process industries and blends of refrigerants,1–3 polymers,4,5 and solvents6 are used in a wide range of applications. Solvent mixtures, for example, are used in separation processes, such as extraction,7,8 absorption,9 and crystallisation,10,11 and in chemical reactions.12,13 In product design, the desired performance can often only be achieved with a mixture or formulation (e.g., pesticide formulation, crude oils blended into a single product).14,15 The current regulatory environment is making mixtures increasingly relevant as restrictions are placed on the use of a growing number of compounds. Some common compounds are thus being removed from use as a result of changing regulations (e.g., REACH regulations16). Given this context, the formulation of mixtures offers a potential route to enhanced performance, because mixtures can exhibit properties that equate or even surpass those of pure compounds. Some of the benefits of using mixtures have been demonstrated by Granberg and Rasmuson17 who studied the solubility of paracetamol in a binary mixture of water and acetone. Their composition, remains challenging. The choice of components is often made based on expensive and time-consuming experiments or database searches,21 using databases that include thermodynamic property data collections for pure components and mixtures such as the CAPEC22 database, CHEMSAFE,23 DEHEMA,24 DETHERM,25 DIPPR,26 HSSDS,27 NIST,28 SOLV-DB,29 SSDS,30 TAPP.31 To broaden the search for better mixtures several more systematic approaches for mixture design10,11,14,32–34 based on computer-aided mixture/blend design (CAMbD), have been developed. CAMbD has been defined by Gani and coworkers10,14,35 as the problem of identifying, from a set of given molecules, a mixture with desired properties that optimizes a given performance measure. The general objective of CAMbD is to design the optimal number, identity and compositions of the components that participate in a mixture that meets the design criteria. The vast majority of approaches developed can be used in the context of the hybrid computer-aided
molecular design (CAMD) methodology for molecule or mixture design problems proposed by Harper et al.36 It involves a three-step design process that includes first a predesign phase where the problem is defined, then a design phase that consists of optimizing a performance index subject to property constraints, and finally a postdesign phase where verification and analysis of the results obtained from the design phase take place.

Some studies in the area of CAM bD have been focused on developing new methodologies for formulating and solving the mixture design problem. One set of approaches is based on the use of mixed-integer nonlinear programming (MINLP), and this has mostly been applied to the design of binary mixtures. Such a methodology was presented by Duvedi and Achenie1 who studied the design of environmentally friendly refrigerant mixtures. The authors proposed a mathematical programming problem where the identity of candidate molecules and of the components in the mixture are defined by binary variables, whereas continuous decision variables are used to represent mixture properties and composition. This design methodology was also used by Churi and Achenie2 to design optimal refrigerant mixtures that have the highest cooling effect in a double-evaporator refrigeration system. In this study, optimal binary mixtures that can give higher efficiencies were identified for a refrigeration cycle with two evaporators operating at two different temperatures. Siougkrou et al.37 investigated the design of binary solvent mixtures as part of conceptual process design. Their approach focused on the design of a CO2-expanded solvent and its impact on process performance. They used enumeration to solve the resulting MINLP due to the small number of discrete choices.

A general and systematic methodology based on an MINLP formulation was also proposed by Vaidyanathan and El-Halwagi4 for the design of polymer blends, where binary polymer mixtures that match a set of target properties were determined. In the resulting design problem, the identity and the compositions of the components in the mixture were considered as decision variables. Local solutions of the problem were obtained with commercial software packages and an example of small dimensionality was solved globally using an optimization algorithm based on interval analysis.

Much effort has also been devoted to developing strategies that can address the complexity of the MINLP mixture design problem. An interval-analysis based optimization framework was developed by Sinha et al.38,39 to solve such problems. In their study, an eight-step interval-based domain reduction algorithm, LIBRA, was developed and used successfully to identify the globally optimal binary mixture in the design of environmentally acceptable blanket wash solvent blend. The solvents that participate in the mixture were selected from a list of promising candidates.

Several authors have developed decomposition-based approaches in which the search space is gradually narrowed. A decomposition-based computer-aided molecular/mixture design methodology was proposed by Karunanithi et al.10 Within their framework, the original mixture design problem is decomposed into the five following nonlinear subproblems: (1) structural constraints, (2) pure component property constraints, (3) mixture property constraints, (4) miscibility constraints, and (5) process model constraints and objective function (MINLP subproblem). In each subproblem, pure components and/or mixtures that do not satisfy a subset of the constraints of the original problem are eliminated. This leads to a smaller final MINLP problem, in which a large portion of the search region has been eliminated. This decomposition-based methodology was later applied by the same authors to the design of crystallization solvents.11 Their study involved the design of optimal binary solvent mixtures that maximize the potential recovery of a drug, subject to several property constraints, such as crystal morphology, solubility, viscosity, toxicity, normal boiling point and melting point.

Buxton et al.40 proposed a systematic decomposition-based procedure to select optimal solvent blends for nonreactive, multicomponent gas absorption processes. Their approach was based on an extension of the work of Pistikopoulos and Stefanis,3 who considered the design of pure solvents for environmental impact minimization. Within their proposed framework, process operations that make use of solvents are identified first and the solvent candidates are then determined subject to specific property and environmental constraints. Finally, the performance of the solvents is verified on a plant-wide basis and the optimal solvent candidate is selected. The extension of this formulation to the design of binary solvent mixtures40 requires the inclusion of additional constraints on the physical properties and the operating conditions.

In the recent work of Papadopoulos et al.,33 a CAM bD approach was developed as a Multi-Objective Optimization problem (MOO) for obtaining the optimal binary fluid mixture for organic Rankine cycles. In this approach, the two compounds and their optimal composition in the mixture are designed simultaneously using a two-stage methodology. In the first part, the molecular structure of a pure compound that matches a set of properties and yields the best performance measure is designed; this compound is then selected to be the first component in the binary mixture. The second stage consists of designing a number of feasible molecules for the second component in the mixture and defining the optimal mixture composition. The proposed mixture design methodology is followed by a nonlinear sensitivity analysis to evaluate the effect of the uncertainties arising from the model and in particular from the use of group contribution methods. A useful feature of this approach is that the first component is guaranteed to be a good fluid, so gives good baseline performance, and the second component is guaranteed to provide a performance enhancement, regardless of its performance as a pure compound. In principle, this means that, if this framework was applied to the design of a solvent mixture that maximizes the solubility of paracetamol, a binary mixture with the characteristics of the acetone and water mixture (of Figure 1) could be

![Figure 1. Solubility, C_{acet}, of paracetamol in a mixture of water + acetone, at 30°C, as a function of the mass percent of water in the solvent. Units of solubility: g of paracetamol/kg of solvent.]

17
identified. Acetone, which is considered to be a good solvent, could be identified in the first part of the methodology and water, which improves the overall performance, could be determined in the second part.

Only a few methods have been proposed to address the design of mixtures with more than two components. This issue was studied systematically by Klein et al., with a proposed nonlinear programming formulation of the problem. In this work, the objective was to determine the minimum cost solvent mixture, subject to linear constraints on the solubility parameters and nonlinear constraints on the density and boiling-point temperature. The candidate solvents were selected from a predefined set of molecules.

Recently, Ng et al. presented a two-stage methodology for mixture design in an integrated biorefinery. The first stage consists of the mixture design framework, where optimal mixtures are formulated based on standard CAMBD techniques. First, the component that performs the main functionality of the mixture is identified from given products or designed with respect to physico-chemical properties and structural constraints. Next, based on the target properties (product needs), the number of components to participate in the final mixture is defined, and suitable additive components that meet these properties are then designed. In the final part of this stage, the miscibility of the mixture components is investigated. In the second stage, the optimal biomass conversion pathways that produce the optimal mixtures determined in the first stage are identified using a superstructure optimization approach. The design methodology was applied to case study for the design of biofuels from palm-based biomass.

A systematic four-step methodology applicable to more than two components was proposed recently by Yunus et al. for the design of blended liquid products. The first step consists of the definition of the problem, where the product needs are identified and translated into physico-chemical target properties, and target values for these properties are determined. In the next step, a set of property models is retrieved from the model library to allow the prediction of pure component and mixture target properties. The third step involves the design of multi-component mixtures based on a decomposition methodology, where pure components that satisfy the property constraints are first identified and then a stability analysis is performed to define possible mixtures. The third step is concluded by optimizing the performance objective subject to the linear and nonlinear property models. The mixture design methodology is applied to binary and ternary mixtures. In the fourth and final step, rigorous models are used to verify the mixture property values, resulting in a set of optimal blends that satisfy all property targets. The proposed methodology was applied to two case studies: (a) designing gasoline blends that can be used in car engines in hot climates and (b) designing environmentally friendly base-oil mixtures that have good lubrication properties, from organic chemicals and mineral oils.

In spite of these advances, there remains significant scope for further research in this area. Most existing methodologies are applicable to binary mixtures only, with the exception of the work of Klein et al., and Yunus et al. Furthermore, in many methods the space of possible components is restricted. In some cases, all components that participate in a mixture are selected from a given set of molecules, while in others, one of the mixture ingredients is defined a priori, and the other compounds (usually one compound) are designed or selected from a set. In these methodologies, the number and the identity of one component (or of all components) are usually chosen in advance, and then the identities of the remaining molecules in a mixture, their compositions, and, where relevant, process topology and operating conditions, are defined. In this sequential approach, where the desired number of mixture ingredients is specified and a single compound is selected from a given list, there is a risk of excluding from the design space molecular structures which, when combined in a mixture, can lead to better performance. Only a small number of studies are reported in the literature in which the simultaneous design of all compounds is considered. However, these studies refer to problems where the number of mixture ingredients is fixed to two. In summary, a reduced version of the general CAMBD problem has been addressed to date: the number of mixture ingredients is fixed (usually 2) and the identity of a compound (or in a few cases, of all compounds) that can participate in a mixture is chosen from a given set of candidate molecules.

A hurdle in the further development and widespread use of tools for CAMBD is the complexity of the mathematical programs that need to be formulated and solved. When modeling a mixture design problem directly as a MINLP problem, several numerical difficulties can arise, related to the nonlinearity (nonconvexity) of the property models and the large design space. Solving the optimization problems can be quite challenging, as these are combinatorial due to the presence of binary variables, and highly nonlinear due to the expressions that relate composition, structure and physical properties.

In view of these challenges, the main purpose of this article is to create a comprehensive and systematic mathematical programming approach for the formulation and solution of the general CAMBD problem. To address the difficulties arising from the complexity of expressing the problem within a mathematical framework, we adopt a logic-based methodology in which generalized disjunctive programming (GDP) is used to formulate the discrete choices inherent in mixture design problems. In this framework, we first show how to formulate a design problem in which the number of components (N) in the mixture is fixed and these components are selected from a predefined set of molecules. In working toward the generalized CAMBD problem, we focus on making N a design variable where at most Nmax compounds are chosen from a given list. This design methodology is an initial approach to a more general concept where the simultaneous design of the number, identity and compositions of mixture ingredients will be considered. Our proposed logic-based approach fits within the broader framework proposed by Harper et al. and can be used in the second (design) step of such an approach.

This article is organized as follows: first, the background theory is given, including a brief introduction to the CAMBD framework, followed by a short description of GDP. The general methodology used in this work and a detailed description of the proposed formulations are presented in the next section. The concepts are applied to a case study of solvent mixture design. The optimal solvent mixture that maximizes the solubility of ibuprofen is identified under different scenarios, with the components being selected from a list of compounds. The conclusions of this work are summarized in the final section.

**Modeling Approaches**

**Computer-aided mixtureblend design (CAMBD)**

The many systematic approaches that have been derived for the design of compounds that exhibit desirable performance
are known collectively as CAMD methods. The CAMD concept was initially introduced by Gani and Brignole in 1983\textsuperscript{7} and has since been significant progress toward this goal.\textsuperscript{9,10,14,33,35,36,44–46} In the case of mixture design applications, a CAMD problem is expanded into computer-aided mixture/blend design (CAM\textsuperscript{D}D) problem, usually by including additional mixture property constraints in a “standard” MINLP CAMD problem. Achenie and coworkers\textsuperscript{10,14,35} defined CAM\textsuperscript{D}D as follows:

“Given a set of chemicals and a specified set of property constraints, determine the optimal mixture and/or blend.”

The main objectives of the CAM\textsuperscript{D}D framework focus on optimizing the physical properties of mixtures or compounds\textsuperscript{37,38} and/or on optimizing process performance, such as minimizing process cost\textsuperscript{40} or maximizing production.\textsuperscript{50,51}

As discussed in the introduction, most existing CAM\textsuperscript{D}D methods involve formulating and solving a problem using mathematical programming techniques; usually a MINLP problem. According to Karunanithi et al.,\textsuperscript{10} a general CAM\textsuperscript{D}D problem can be formulated as an MINLP problem as follows

$$
\min \ f(x, y) \\
\text{subject to} \\
g_1(y) \leq 0 \\
g_2(y) \leq 0 \\
g_3(x, y) \leq 0 \\
g_4(x, y) = 0 \\
x \in \mathbb{R}^n, \ y \in \{0, 1\}^m
$$

where \(f\) is the objective function to be optimized (minimization is assumed without loss of generality), subject to structural constraints \((g_1(y))\), pure component property constraints \((g_2(y))\), mixture property constraints \((g_3(x, y))\), and process model constraints \((g_4(x, y))\). The vector \(x\) is an \(n\)-dimensional vector of continuous variables denoting operating conditions, physical properties, or process variables (e.g., flow rate, temperature) and \(y\) is an \(m\)-dimensional vector of binary variables related to the functional groups present in the molecules and/or the identities of the molecules.\textsuperscript{10,35} While the general form of a CAM\textsuperscript{D}D problem is relatively simple and similar to that of a CAMD problem, the formulation of a specific instance of CAM\textsuperscript{D}D as an MINLP is a challenging task because of the different types of binary or integer variables involved and their strong interactions with the often-nonlinear physical property models.

**Generalized disjunctive programming**

An alternative approach for formulating discrete/continuous optimization problems, known as GDP, was introduced by Raman and Grossmann\textsuperscript{43} and has since been successfully applied by Grossmann and coworkers in many different contexts including complex process networks,\textsuperscript{43,52} strip-packing,\textsuperscript{53} and scheduling problems.\textsuperscript{43,53,54} GDP is a logic-based methodology that extends the disjunctive programming proposed by Balas\textsuperscript{55} and involves Boolean and continuous variables that are related via disjunctions, algebraic equations, and logic propositions.\textsuperscript{46–60}

**GDP Formulation.** The general formulation of a generalized disjunctive program can be represented as follows

$$
\min_{x, y} \ f(x) \\
\text{s.t. } g(x) \leq 0 \\
\forall j \in J \left( \begin{array}{c} Y_j \ (x) \\ h_{j,k} (x) \end{array} \right) \leq 0 \quad k \in K \\
\forall j \in J, \ k \in K \quad \Omega(Y) = \text{True} \\
x \in [x^L, x^U] \subset \mathbb{R}^n \\
Y_{j,k} \in \{1, 0\}, \ j \in J, \ k \in K
$$

where \(x\) is a vector of continuous variables, \(x^L\) and \(x^U\) are vectors denoting the lower and upper bounds on \(x\), respectively, and the \(Y_{j,k}\)’s are the Boolean variables that indicate whether a term \(j\) in a disjunction \(k\) is True or False. The objective function \(f(x)\) depends on the continuous variables, and the logic in the continuous space is represented by a set of disjunctions. Each disjunction consists of a number of terms that are joined by the OR (\(\lor\)) operator. Each term of the disjunction has a Boolean variable \(Y_{j,k}\) and only one of the Boolean variables can be True in each disjunction \(\forall j \in J\). \(K\) is the index set for the disjunctions and \(J\) is the index set of the terms in each disjunction \(k \in K\). The function \(g(x)\) represents general constraints that must hold regardless of the logic, while \(h_{j,k}(x)\) are conditional constraints that hold when \(Y_{j,k}\) is True. In mixture design problems the disjunctive constraints are related to the assignment of compounds and the number of components that participate in a mixture. \(\Omega(Y)\) represents logic relations for the Boolean variables expressed as propositional logic.\textsuperscript{61}

It should be mentioned that any MINLP problem can be formulated as a GDP problem and vice versa. It may be beneficial to adopt a GDP formulation because, when compared with mixed-integer programming, it provides a more structured framework for modeling discrete-continuous choices and it expresses more directly both the quantitative and the qualitative parts of the optimization task.\textsuperscript{62,63} In an MINLP problem (Eq. 1) the logic needs to be expressed through the objective function and algebraic constraints, in the form \(f(x, y)\) and \(g(x, y)\), respectively. In GDP, conversely, the logic is captured inside the disjunctions by relating Boolean variables \((Y_{j,k})\) to equations in the continuous form \((h_{j,k}(x))\), whereas the logic that connects the disjunctive sets is expressed through the relations \(\Omega(Y)\).\textsuperscript{64} To formulate a general mixture design problem (Eq. 1) as a GDP, several characteristics of the constraints must be taken into account. The constraints that do not depend on the logic conditions can be formulated as general constraints \((g(x))\), whereas the constraints that depend on the logic conditions, such as on the assignment of compounds or on the number of components in a mixture, are formulated within the disjunctions as conditional constraints \((h_{j,k}(x))\).

**Reformulation of GDP as an MINLP.** Once an appropriate GDP formulation has been obtained, it can be converted into an MINLP problem using different approaches, such as big-M or hull relaxation, that result in relaxations of varying strength.\textsuperscript{64,65} The big-M (BM) formulation\textsuperscript{66} is the simplest representation of a GDP problem in a mixed-integer form.\textsuperscript{43,60}
The general reformulation of a GDP as an MINLP via big-M is given by

$$\begin{align*}
\min_{x} & \quad f(x) \\
\text{s.t.} & \quad g(x) \leq 0 \\
& \quad h_{j,k}(x) \leq M_{j,k}(1-y_{j,k}), \quad j \in J_k; \ k \in K \\
& \quad Ay \leq b
\end{align*}$$

where \( y \) is a vector of binary variables, which has one-to-one correspondence with the Boolean variable vector, \( Y, A \) is an \( m \times n \) matrix, \( b \) is an \( m \)-dimensional real-valued vector and the parameter \( M_{j,k} \) is a “sufficiently large” upper bound. The logic propositions in GDP, \( \Omega(Y) = \) True, have been converted into linear inequalities, \( Ay \leq b \). The tightest value for \( M_{j,k} \) can be calculated as \( ^{32} \)

$$M_{j,k} = \max \{ h_{j,k}(x) \mid x^J \leq x \leq x^U \}, \quad j \in J_k; \ k \in K$$

GDP Formulation of the CAMbD Problem

The design methodology proposed in our work integrates GDP into a computer-aided mixtureblend design (CAMbD) framework.

Problem definition

The aim of this study involves the generic formulation of mixture design problems to find the optimal number of mixture ingredients, the optimal identities of the components (chosen from a given list) and their compositions, such that all given specifications are satisfied and the specified performance objective is optimized.

The problem formulation is constructed in a systematic way by considering two problem statements of increasing complexity. The first class of problems involves the formulation of a restricted model, where a fixed number of components is identified from a given set of candidate compounds, subject to property constraints. The design variables are the identity of the components that participate in the mixture and their compositions. After establishing the solution of this restricted problem, we propose a second, more general formulation, where the number of components in the mixture is not fixed but is bounded by an upper limit. The optimal components are again selected from a predefined set of components. In the general problem the decision variables are the number of components, their identities, and their compositions.

To develop the formulations, we define several index sets. The first is the set of components in the mixture, \( I = \{ i \mid i = 1, \ldots, N_c \} \), where \( N_c \) is the total number of components. The second set \( S = \{ s \mid s = 1, \ldots, N_s \} \) defines the list of compounds from which the mixture components must be chosen, where \( N_s \) is the total number of molecules in the list. The mixture to be designed often contains components that are known a priori (e.g., solutes in the case of solvent design). We define \( N' \) as the number of fixed components and \( N \) as the (maximum) number of components to be designed. The total number of components in the mixture is thus \( N_c = N + N' \). For clarity, we use the term “components” to refer to the ingredients/molecules in the mixture we are designing and the term “compounds” to refer to ingredients/molecules in the set \( S \) from which we choose the components. Those components in the mixture that are not fixed (i.e., components \( N' + 1 \) to \( N_c \)) are referred to as the “designed components.”

Formulation for known number \( N_c \) of components in mixture

The discrete choices of the restricted mixture design problem with a fixed value of \( N \) are modeled using GDP. The GDP formulation of the restricted problem includes disjunctions for each choice of components and logic propositions that express the relationships between the disjunctive sets.

Disjunctions for Assignment of Components. In a logic-based modeling framework, the assignment of component \( i \) is determined through Boolean variable \( Y_{i,s} \), which is True if a compound \( s \) is assigned to component \( i \) in the mixture and False if it is not, for \( i = N' + 1, \ldots, N_c \) and \( s = 1, \ldots, N_s \). The disjunctions for the assignment of each component are given below

$$\begin{align*}
\bigvee_{i \in S} & \quad Y_{i,s}, \quad i = N' + 1, \ldots, N_c \\
Y_{i,s} \in \{ \text{True, False} \}
\end{align*}$$

The vector \( h_{i,s} \) in each disjunction represents the constraints that are active when compound \( s \) is assigned to \( i^{th} \) component in a mixture. The expression \( \bigvee_{i \in S} Y_{i,s} \) ensures that only one disjunction is active, which means that each component is assigned exactly one compound. It can be translated into algebraic equations by introducing a binary variable \( y_{i,s} \) as follows

$$\sum_{i \in S} y_{i,s} = 1, \quad i = N' + 1, \ldots, N_c$$

Logic Propositions. Logic conditions \( \Omega(Y) = \) True are included to avoid degeneracy by enforcing a specific ordering of the compounds. Degeneracy can be prevented by the following relations that ensure that the relative position of a compound in the set \( S \) is maintained in the mixture (set \( I \) if the compound is selected

$$\begin{align*}
Y_{i,s} & \Rightarrow \neg Y_{i',s'}, \quad i = N' + 1, \ldots, N_c - 1; \ s = 2, \ldots, N_s \\
i' & = i + 1, \ldots, N_c; \ s' = 1, \ldots, s
\end{align*}$$

where the symbol \( \neg \) implies negation (i.e., not \( Y_{i,s} \) or \( Y_{i',s'} = \) False). They are translated into algebraic equations as follows

$$y_{i,s} + y_{i',s'} \leq 1, \quad j = N' + 1, \ldots, N_c - 1; \ s = 2, \ldots, N_s$$.\n
$$i' = i + 1, \ldots, N_c; \ s' = 1, \ldots, s$$

The constraints in Eq. 5 restrict the feasible space by eliminating identical degenerate solutions. Logic conditions are also derived to ensure that each candidate compound is selected at most once

$$\begin{align*}
Y_{i,s} & \Rightarrow \bigvee_{i' \neq i; s' \neq s} Y_{i',s'}, \quad i = N' + 1, \ldots, N_c; \ s \in S
\end{align*}$$
components in mixture

The optimal number of mixture components in the mixture, the identities and compositions of the components, and logic propositions that express the relationships between the disjunctive sets.

Disjunctions for Assignment of Components. The same Boolean variables, \( \psi_{i,s} \), as in the restricted problem, are used to establish the selection of a compound for each component for \( i = N' + 1, \ldots, N_c \) and \( s = 1, \ldots, N_g \). The disjunctions for assigning each component are given by the expression (R-D).

The general formulation at least one designed component should be present in the mixture (i.e., exactly one Boolean variable for assigning a compound to the first component is active). The assignment of exactly one compound to the first designed component in the mixture is given by

\[
\bigvee_{s \in S} \psi_{N' + 1, s} \leq 1
\]

and its algebraic form is

\[
\sum_{s \in S} \psi_{N' + 1, s} = 1.
\]

The rest of the components are assigned compounds from the list only if they are participating in the mixture.

Disjunctions for the Number of Components. The number of components in the mixture is a discrete choice and it is expressed as a series of disjunctions. A vector \( \psi_{n} \) of Boolean variables that express the logic in each disjunction is introduced. Property constraints that depend on the number of components in the mixture are included in each disjunction and they are activated when the corresponding Boolean variable \( \psi_{n} \) takes the value of True. The disjunctions for the number of designed components in the mixture are given by

\[
\psi_{n}(x) = \begin{cases} 
\tilde{Y}_{n} & \text{if } Y_{n} = \text{True} \\
0, & \text{otherwise}
\end{cases}
\]

where \( \tilde{F}_{n}(x) \) is a vector of disjunctive constraints that depend on the number of components in the mixture and are active if \( Y_{n} = \text{True} \). \( x_{i} \) is the mole fraction of component \( i \) in the mixture and is greater than a threshold value \( x_{i}^{L} \) if the component is present in the mixture and is zero otherwise. Exactly one disjunction for the number of designed components must be selected, as shown below

\[
\psi_{n}(x) = \begin{cases} 
\tilde{Y}_{n} & \text{if } Y_{n} = \text{True} \\
0, & \text{otherwise}
\end{cases}
\]

and it is transformed into the following constraint

\[
\sum_{n=1}^{N_{max}} \tilde{Y}_{n} = 1
\]

where \( \tilde{y}_{n} \) is a binary variable equivalent to \( \tilde{Y}_{n} \).

Logic Propositions. Logic conditions to avoid degeneracy are also required in the general formulation. A specific ordering of the compounds is enforced using the same logic propositions as were described in the restricted problem, i.e., Eq. 4. Equation 6 is also used in the general model to ensure that each candidate compound is selected at most once. Additional
logic conditions are required that at most one compound is assigned to components $N'+2$ to $N_c$.

$$Y_{i,s'} \Rightarrow \neg \left( \bigvee_{s=1}^{N_c-1} Y_{i,s} \right) \quad s' \in S \quad i=N'+2, \ldots, N_c$$  
(12)

This is written equivalently as:

$$\sum_{i=1}^{N_c} Y_{i,s} \leq 1 \quad i=N'+2, \ldots, N_c$$  
(13)

This differs from the corresponding constraint in the restricted formulation (Eq. 3) where equality was enforced. Logic propositions are also derived to relate the Boolean variables for the number of designed components in the mixture, $Y_{i,s} \in \{1, \ldots, N_{max}\}$ to the Boolean variables for the assignment of a compound to each component, $Y_{i,s}, s=N'+1, \ldots, N_c; \ s=1, \ldots, N_c$. We represent the number of designed components in the mixture by the Boolean variables $Y_{i,s} (i=1, \ldots, N_{max})$ such that:

- $Y_{i,s}$ denotes the logic relations in Table 1. As described by Raman and Grossmann, the above expressions are replaced by their equivalent disjunctions and the “OR” operator is distributed over the “AND” as described by Raman and Grossmann. As shown in Table 1, the resulting clauses can then be expressed as a set of linear inequality constraints by replacing the Boolean variables with binary ones.

**GDP Formulation.** The GDP formulation of the general model can be written as:

$$\min_{x,y} f(x)$$

s.t. $g(x) \leq 0$

$$\forall s \in S \left[ Y_{i,s} \right]_{i=N'+1, \ldots, N_c}$$

$$h_{i,s}(x) \leq 0$$

$$\forall n=1, N_{max}$$

$$\tilde{Y}_n \leq 0$$

$$\forall s=1, N_{y_i}$$

$$Y_{i,s} \Rightarrow \neg Y_{i,s'}, s=N'+1, \ldots, N_c; \ s=2, \ldots, N_s$$

$$i'=i+1, \ldots, N_c; \ s'=1, \ldots, s$$

$$Y_{i,s} \Rightarrow \neg \left( \bigvee_{i'=1}^{N_c} Y_{i,s'} \right) \quad s=1, \ldots, N_{max}$$

$$\Omega(Y)=\text{True}$$

$$\left[ x_{N'}+1 \right] \geq \left[ x_{N'} \right]_{N_{y_i}+1}$$

$$x_i \in [x_i^L, x_i^U] \in \mathbb{R}, \ i=N'+1, \ldots, N_c$$

$$Y_{i,s}, \tilde{Y}_n \in \{\text{True, False}\}, i=N'+1, \ldots, N_c; \ s=1, \ldots, N_{max}$$

(G-GDP)

where $\Omega(Y)=\text{True}$ denotes the logic relations in Table 1. As at least one component should be present in the mixture, the mole fraction of the first designed component ($x_{N'+1}$) has always a non-zero value.

**Reformulation of GDP as an MINLP.** Formulation (G-GDP) can be transformed into an MINLP problem using the big-M approach as follows:

$$\min_{x,y} f(x)$$

s.t. $g(x) \leq 0$

$$h_{i,s}(x) \leq M h_{i,s} (1-y_{i,s}), s=1, \ldots, N_s; \ i=N'+1, \ldots, N_c$$

$$\tilde{F}_n(x) \leq M \tilde{F}_n (1-y_{n}), n=1, \ldots, N_{max}$$

$$x_i \geq x_i^L \tilde{y}_n, n=1, \ldots, N_{max}; i=N'+2, \ldots, N_c$$

$$\sum_{s=1}^{N_{y_i}} y_{N'+1,s} = 1$$
The logic relations, \( Q(Y) \) =True, of the GDP model are converted to a set of algebraic constraints, \( Ay \leq b \), by replacing the Boolean variables with binary ones, as shown in the second column of Table 1.

The formulations described in this section are applied to a solvent mixture design case study presented in the next section.

**Case Study: Maximizing the Solubility of Ibuprofen**

Ibuprofen (ibu) is a colorless anti-inflammatory compound that can be crystallized by cooling crystallization.\(^{69}\) Solubility is one of the key properties that determine the performance of the crystallization process.\(^{11,69}\) Karunanithi et al.\(^{11}\) have already addressed the problem of identifying appropriate solvents or solvent mixtures that enhance the crystallization process of ibuprofen. This well-studied application is, therefore, a suitable example to investigate the use of the proposed GDP formulations for CAMB. The objective of the design problem considered is to identify an optimal solvent mixture to maximize the solubility of ibuprofen

\[
\text{max } x_{ibu}
\]

where \( x_{ibu} \) is the mole fraction of ibuprofen in the mixture. The first important set of constraints in formulating the problem captures the relationship between the solvent mixture and the solubility of ibuprofen, via solid–liquid equilibrium. Although phase equilibrium relations involve complex nonlinear functions, in this case study only ibuprofen is at solid–liquid equilibrium, whereas all solvent molecules in the mixture are in a single liquid phase. Therefore, the solubility, which depends on the enthalpy of fusion and melting temperature of the solid and its liquid-phase activity coefficient, is expressed in terms of ibuprofen and calculated as follows:\(^{70,71}\)

\[
\ln x_{ibu} + \ln \gamma_{ibu} = \frac{\Delta H_{\text{fus}}}{R} \left[ \frac{1}{T_m} - \frac{1}{T} \right]
\]  

(14)

where \( \gamma_{ibu} \) is the liquid phase activity coefficient of ibuprofen at temperature \( T \), composition \( x \) and pressure \( P \). \( R \) is the gas constant, \( \Delta H_{\text{fus}} \) is the enthalpy of fusion of ibuprofen at temperature \( T_m \), and \( T_m \) and \( T \) are the normal melting point of ibuprofen and the mixture temperature, respectively. The pressure is assumed to be atmospheric (\( P = 1 \text{ atm} \)). The activity coefficient is evaluated using the UNIFAC\(^{70,72}\) group contribution method, and it is calculated as the sum of two contributions, a combinatorial term (superscript \( C \)) and a residual term (superscript \( R \)), as shown below

\[
\ln \gamma_{ibu} = \ln \gamma_{i}^{C} + \ln \gamma_{ibu}^{R}
\]

(15)

The UNIFAC model proposed by Smith et al.\(^{73}\) in a form convenient for implementation is used in this design problem and the relevant equations are presented in Appendix A for completeness.

The mutual miscibility of the solvent molecules also needs to be examined to ensure that the final mixture is in one phase. However, algebraic relations to describe this constraint are not available for multicomponent systems and, therefore, in common with other works,\(^{10,11,40}\) a miscibility constraint for every binary pair of solvent molecules is used in this case study (i.e., each binary pair of solvents must be miscible for the chosen relative composition, temperature, and pressure).\(^{73}\)

\[
\frac{\partial \ln \gamma_{ij}}{\partial \ln x_{ij}} + \frac{1}{x_{ij}} \geq 0, \quad i < j
\]

\[
i = N' + 1, \ldots, N - 1
\]

\[
j = i + 1, \ldots, N_c
\]

(16)

where \( \gamma_{ij} \) denotes the activity coefficient of component \( i \) in a binary mixture of \( i \) and \( j \) at temperature \( T \) and pressure \( P \), and \( x_{ij} \) denotes the mole fraction of component \( i \) in the mixture of \( i \) and \( j \). It is related to the mole fraction in the multicomponent mixture by

\[
x_{ij} = \frac{x_i}{x_i + x_j}
\]

Scenarios considered

We consider several instances of the case study, with varying complexity. In particular, numerical difficulties may arise due to the highly nonlinear nature of the miscibility function. To reduce the complexity of the model, two main scenarios are considered: in the first, simpler, scenario the miscibility constraint is not taken into account, whereas in the second scenario it is included in the model. For both scenarios, the two formulations proposed in the section on the GDP formulation of the CAMB problem are applied: the restricted problem, where the number of components to be selected is fixed and the general problem, where the number of components in the mixture is unknown. With the restricted problem formulation, mixtures with one, two or three solvents are designed (i.e., \( N_c = 2, 3, \) or \( 4 \)). With the general problem formulation, a mixture with at most three solvents is identified (i.e., \( N_{\text{max}} = 3 \)). The solvents are to be selected from a list of nine candidate compounds.

All the design sets used in this case study are shown in Tables 2 and 3, and the list of candidate solvents is shown in Table 4. Although a list of promising pure solvents in which ibuprofen has a high solubility has sometimes been used in previous work,\(^{10,11}\) a list of common solvents that yield a range of solubilities is used in this work to investigate mixtures where one compound is a poor performer when used on
its own, but may lead to high solubility values in a mixture. The solvent molecules in the list were chosen based on their low toxicity levels and on their liquid range, ensuring that they are liquid at the chosen conditions of $T = 300$ K and $P = 1$ atm. A table with experimental data for toxicity, and boiling and melting points is presented in Appendix B. The candidate solvents are often used in industrial applications and are also reported in studies of the solubility of various solid organic compounds in pure solvents.\(^7\) The problem-specific parameters required are the enthalpy of fusion of ibuprofen (25.5 kJ/mol\(^7\)) and its normal melting point (347.15 K\(^7\)). The solvent molecules and ibuprofen are built from the set of functional groups given in Table 5. The number of groups of type $k$ in ibuprofen ($\text{Vib}_k$) and in a solvent $s$ ($\text{V}_{s,k}$) is presented in Appendix C in Tables C1 and C2, respectively. The group volume parameters ($R_k$), the group surface area parameters ($Q_k$) and the group interaction parameters ($a_{km}$) used in the UNIFAC model for the prediction of the activity coefficient are obtained from Poling et al.\(^7\)\(^6\) and listed in Appendix C (Tables C3–C5) for completeness.

**Task 1: Mixture design without miscibility constraints**

The formulations of the restricted and general problems, without the miscibility constraint, are presented in this section. The objective here is to maximize the solubility of ibuprofen and the objective function, therefore, consists of the mole fraction of ibuprofen in the mixture (i.e., $f(x) = x_{\text{ibu}}$). General constraints refer to equations that do not depend on the logic choices and they include the solubility (Eq. 14) and activity coefficient (Eq. 15) relations that are expressed in terms of ibuprofen, as well as some equations of the UNIFAC model (Eqs. A2–A4, A7–A9, A12, and A13) from Appendix A. Conditional constraints, such as the identities and compositions of the selected solvent molecules that depend on the assignment and/or number of solvents in the mixture, are included in the appropriate disjunctions, as shown in the next paragraphs.

**Restricted Problem: Fixed Number of Solvents.** This problem aims to identify the optimal mixture of components for a fixed number of solvent molecules (i.e., 1, 2, or 3 selected solvents), along with the mixture composition, to maximize the solubility of ibuprofen. The formulation is presented for the selection of three solvents but it can readily be extended to any fixed number of solvents. The disjunctions for the choice of solvents are shown below

Table 4. List of Candidate Solvents

where $v_{s,k}$ defines the identity of the solvents, that is, $v_{s,k}$ represents the number of groups of type $k$ in solvent $s$; $n_{i,k}$ gives the identity of designed component $i$ in the mixture, that is, $n_{i,k}$ represents the number of groups of type $k$ in designed component $i$. The variables $r_i$ and $q_i$ are the molecular van der Waals volume and molecular surface area of component $i$, respectively, while $r_i$ and $q_i$ are the van der Waals volume and surface area, respectively, for compound $s$ in the solvent list. In the above disjunctions, only one of the Boolean variables $Y_{i,s}$ can be selected, which ensures the selection of exactly three solvents. To express disjunction (R-D1) algebraically, the identity of component $i$, $n_{i,k}$, is defined by the use of the binary variable $y_{i,s,k}$, multiplied by the identities of all available candidates, $v_{s,k}$. Similarly, $q_i$ and $r_i$ are expressed as products of $y_{i,s,k}$ with $q_i$ and $r_i$, respectively, as shown below

$\begin{align*}
Y_{i,s,k} & = v_{s,k}, \quad k \in K \\
q_i & = q_{i,s} \\
r_i & = r_{i,s}
\end{align*}$

These relations force the above variables ($n_{i,k}$, $q_i$, $r_i$) to become zero when a solvent is not chosen, avoiding the use of the big-M parameter in the MINLP reformulation for this simple case.

The logic conditions discussed in the section on the GDP formulation of the CAMbD problem (Eqs. 4 and 6) are derived to avoid selecting a given candidate solvent more than once, and to avoid degeneracy by ordering the solvents. After removing the disjunctions (R-D1) and including all the logic conditions expressed as algebraic equations, the resulting MINLP reformulation is given by model (R-BM1) in Appendix D.

**General Problem: Unknown number of solvents.** The formulation is extended to the general case where the number of mixture constituents is not known in advance. Hence, the design variables include the number of components in the mixture, their identities and compositions. As the number of solvent components present in the mixture is allowed to vary from one to three solvents, the maximum number of designed components in the mixture is $N_{\text{max}} = 3$.

The problem includes disjunctions for the assignment of each candidate solvent and disjunctions for the number of

selected solvent. The former disjunctions are the same as those presented in the restricted problem (disjunctions \([R-D1]\)). In the general problem exactly one of the Boolean variables for assigning one solvent to the first designed component in the mixture is active. The disjunctions for the number of components include constraints that depend on the number of solvents selected, as shown below

\[
\forall i=1,2,3 ~ \begin{cases} 
\tilde{Y}_i \\
\tilde{n}_{ij} = n_{ik}, & i \in I_i; \ k \in K \\
\tilde{q}_i = q_i, & i \in I_i \\
\tilde{r}_i = r_i, & i \in I_i \\
x_i \geq 0.001, & i \in \{c_2, c_3\} \\
x_i = 0, & i \notin (I_1 \cup \{ibu\}) \\
\text{where} & \\
I_1 = \{c_1\} \\
I_1 = \{c_1, c_2\} \\
I_1 = \{c_1, c_2, c_3\} 
\end{cases}
\]  

\( (G-D1) \)

As mentioned in the section on the GDP formulation of the CAMD problem, at least one designed component should be present in the mixture and, therefore, the mole fraction of the first solvent component \(x_{c_1}\) is always strictly greater than zero. In the general problem only one disjunction for the number of solvents is selected. The GDP formulation is converted into an MINLP model (G-BM1) via the big-M approach as presented in Appendix D. Variables \(\tilde{n}_{ij}, \tilde{q}_i, \tilde{r}_i\) in the above disjunctions are linked to disjunctions \((R-D1)\) via \(n_{ij}, q_i, r_i\), which become zero when a solvent is not selected. It is thus sufficient, for the reformulation of the problem, to derive big-M equations only for the mole fractions \(x_i\) of designed components in the mixture, based on the binary variables for the number of components. A lower bound equal to 0.001 is used to express the mole fraction via big-M approach. It should be noted that Eqs. A5, A6, and A11 of the UNIFAC model (Appendix A), also depend on the number, \(N\), of solvent components in the mixture. These functions, however, can be placed outside of the disjunctions as the dependence on \(N\) can be captured via \(\tilde{n}_{ij}, \tilde{q}_i, \tilde{r}_i\), and their formulation does not lead to numerical difficulties provided that at least one solvent component is present in the final mixture and has a non-zero mole fraction. This is achieved by setting a lower bound for \(x_i\) (the first designed component) of 0.001. We also set \(x_i = 0.001\) for \(i=c_2, c_3\). Following the formulation steps outlined in the section on the GDP formulation of the CAMD problem, logic conditions that establish the relationships between the disjunctive sets (Eqs. 4, 6, 12, and \(\Omega (Y)\) in Table 1) are also derived. Valid upper bounds can readily be derived for the big-M parameters \((M_{ri}, M_{ri})\) using Eq. 2. The upper bounds used in this case study are relaxed bounds rather than exact bounds, to avoid numerical difficulties arising from tight bounds and machine precision.

**Task 2: Mixture design with the miscibility constraint**

In this task, the introduction of the highly nonlinear and nonconvex miscibility function increases the complexity of the formulations and makes their solution quite challenging.

**Restricted Problem: Fixed Number of Solvents.** The restricted problem is formulated in the same fashion as for the first task and it consists of the objective function \(\{x_{au}\}\), solubility (Eq. 14), activity coefficient (Eq. 15) and miscibility (Eq. 16) constraints, and the logic relations Eqs. 4 and 6. The miscibility function is calculated for every binary pair of designed components, that is, for the pairs \((c_1, c_2), (c_1, c_3), \) and \((c_2, c_3)\) for \(N = 3\), using the composition of the binary mixture derived from the overall mixture composition. Specifically, the miscibility constraint for a mixture of solvents \(i\) and \(j\) is given as

\[
d_{ij}^{\prime} + \frac{1}{x_{ij}^{\prime}} \geq 0, \quad i < j, \ i = c_1, c_2; \ j = c_2, c_3
\]

where \(d_{ij}^{\prime}\) is the derivative of the natural logarithm of the activity coefficient of component \(i\) with respect to the mole fraction of \(i\) in the binary mixture (i.e., \(d_{ij}^{\prime} = \frac{\partial \ln \gamma_i}{\partial x_i}\)) and it is calculated from the UNIFAC model (i.e., \(d_{ij}^{\prime} = (d_{ij}^{\prime})^C + (d_{ij}^{\prime})^R\)). The mole fraction of the solvent \(i\) in the binary mixture \(x_{ij}^{\prime}\) is expressed as

\[
x_{ij}^{\prime} = \frac{x_i}{x_i + x_j}, \quad i = c_1, c_2; \ j = c_2, c_3
\]

where \(x_i\) and \(x_j\) are the mole fractions of components \(i\) and \(j\), respectively, in the overall mixture. Because the total number of components in the mixture is fixed, Eqs. 17 and 18 can be treated as general equations and included outside the disjunctions. The resulting MINLP formulation is given by model \((R-BM2)\) in Appendix D.

**General Problem: Unknown Number of Solvents.** The more general problem formulation requires further adaptation to include the miscibility constraints. Recalling that the problem includes disjunctions for the assignment of the candidate solvents and disjunctions for the number of the solvents selected,
Results and Discussion

The list to mixture components are unchanged from task 1. Conversely, the disjunctions for the number of the solvents selected now include variables and functions that depend on the number of the components in the mixture, such as the composition, the miscibility function and the UNIFAC model equations for evaluating the solvent properties. These functions and the relevant variables are placed in the appropriate disjunctions and are presented as formulation (G-D2) in Appendix D. The logic propositions used in the general problem of task 1 are also included in this task. The disjunctions (G-D2) are reformulated via the big-M approach and the resulting MINLP problem is also given as model (G-BM2) in Appendix D.

It is instructive to consider the computational requirements of the different problem formulations. The values of the CPU time presented in Tables 6–8 correspond to the runs where the best solutions were found and they are representative of all attempts with different initial points. For the problems with a fixed number of mixture components, the CPU time increases rapidly with the number of components, as a result of the increase in the size and complexity of the problems. The introduction of the nonlinear miscibility constraints has little effect on the cost of solving the restricted and general problems locally. Furthermore, enumerating all options for the number of components \( N = 1, 2, \) or \( 3 \) appears to be a more effective strategy than the solution of the general problem from the perspective of computational cost. Further, computational studies are required to investigate whether this finding holds for larger number of components.

Conclusions

Computer-aided mixture design is an important tool that has the potential to improve process and product design, but often leads to challenging mixed integer optimization problems due to nonconvexities in the space of the continuous variables and a large combinatorial solution space. The number of interlinked decisions to be considered makes it difficult to formulate the problem in a way which can be easily understood, modified and solved. A general modeling framework for mixture design problems has been proposed in this work to address these difficulties. Several problem formulations based on the GDP formalism have been presented. They provide a systematic approach to posing CAM²D problems in which the number of mixture components, the identities of the components and their compositions are to be determined. The proposed approach has been applied successfully to a solvent mixture design problem for maximizing the solubility of ibuprofen. The methodology adopted in this case study included two problem formulations: (1) with fixed number of solvents (restricted problem) and (2) with unknown number of components (general problem). Both problems were first solved without taking any miscibility constraint into account in the problem formulation and then including a miscibility constraint for every binary solvent pairs. Logic conditions between the disjunctive sets were expressed as algebraic constraints, whereas disjunctions for the assignment and number of solvent molecules were transformed into mixed-integer constraints using the big-M approach. High quality solutions of all problems were obtained using a local MINLP solver.

The findings from the case study provide evidence of the usefulness and versatility of a GDP-based approach to optimal mixture design. Integrating GDP techniques into the CAM²D framework can facilitate the formulation of the design problem, making it possible to optimize simultaneously the number, identities, and compositions of components in the mixture. Numerical difficulties associated with the absence of components in the final mixture, which are a concern when miscibility constraints are included in the formulation, can be avoided,

we first note that the disjunctions for assigning solvents from the list to mixture components are unchanged from task 1.

Conversely, the disjunctions for the number of the solvents selected now include variables and functions that depend on the number of the components in the mixture, such as the composition, the miscibility function and the UNIFAC model equations for evaluating the solvent properties. These functions and the relevant variables are placed in the appropriate disjunctions and are presented as formulation (G-D2) in Appendix D. The logic propositions used in the general problem of task 1 are also included in this task. The disjunctions (G-D2) are reformulated via the big-M approach and the resulting MINLP problem is also given as model (G-BM2) in Appendix D.

All models were implemented and solved in GAMS77 version 24.2.3, using DICOPT.78–80 which is a local MINLP solver. The models were run on a single core of a dual 6 core Intel Xeon X5675 machine at 3.07 GHz with 48 GB of memory. Due to the highly nonlinear nature of the equations in the models, multiple initial guesses were used to identify good solutions. The best solutions obtained in the first task (i.e., without the miscibility constraint) and in the second task (i.e., with the miscibility constraint) are summarized in Tables 6 and 7, respectively. It can be observed that in the restricted problem for both tasks, the best solution is yielded by a mixture of two solvents. In the formulations where the miscibility function was not included, a mixture of chloroform and water was identified as the optimal solvent mixture, whereas a binary mixture of chloroform and methanol was identified as optimal when the miscibility constraint was added. Indeed, the miscibility constraint is not satisfied for the pair of chloroform and water at the optimal composition of task 1. Chloroform and methanol, conversely, are fully miscible. The mixtures with three components give slightly lower solubility than the mixtures with two components. In these cases, the mole fraction of the third solvent component is at the lower bound. The results obtained when solving the general problem, with \( N \) unknown, validate the solutions obtained in solving the three restricted problems, by confirming that the highest solubility is achieved by a binary mixture, in which the composition of ibuprofen is 0.34928 and 0.33383 in the first and second task, respectively. The results of both tasks show that a higher solubility can be obtained in a mixture of two or three components rather than in a pure solvent.

The problems of the first task, where the miscibility constraint was not included in the formulation, were also solved globally in GAMS, using BARON81 which is a local MINLP solver. The results validate the solutions obtained with DICOPT, by proving that the highest solubility is achieved by the mixture of chloroform and water, as shown in Table 8. The slightly different values of mole fraction observed between DICOPT and BARON are due to the convergence criteria used in each solver. The problems of the second task, where the miscibility of the solvents was taken into account, are more complex and could not be solved to global optimality.

Further, computational studies are required to investigate whether this finding holds for larger number of components.
leading to computationally efficient solutions. In the case study, it was found that mixtures outperform pure solvents.

Future perspectives for this work include developing algorithms to solve these complex design problems globally and using alternative logic-based optimization techniques. The Big-M formulation used in this study is the most common relaxation technique but it is known to give weak lower bounds for a minimization problem.43,82 Other techniques, such as Hull Relaxation, can be used. In the case of convex problems, the resulting bounds are at least as tight or tighter17,85 but the case of nonconvex problems83,84 presents additional challenges. Finally, the formulation of the design problems could be extended to the design of molecules from the basic building blocks (UNIFAC groups) so that the preselection of promising molecules to include in the list of candidates can be avoided.

In this way, a comprehensive approach to mixture design problems can be adopted, where the optimal number of molecules, their identities and compositions are optimized simultaneously.

**C Parameters of the UNIFAC Model used in this Case Study**

The number of groups of type \(k\) in ibuprofen \((v_{\text{ibu}, k})\) and in a solvent \(s\) \((v_{i, k})\) are presented in Tables C1 and C2, respectively; the group volume parameters \(R_k\), the group surface area parameters \(Q_k\), and the group interaction parameters \(a_{m, k}\) used in the UNIFAC model for the prediction of the activity coefficient are listed in Tables C3–C5, respectively.

**D Problem Formulations**

For definition of indices and sets see Table 2.

**MINLP Formulations for Task 1**

*Restricted problem (\(N = 3\))*

\[
\max x_{\text{ibu}}
\]
subject to

\[
\ln x_{ibu} + \ln \gamma_{ibu} = \frac{\Delta H_{ibu}}{R} \left[ \frac{1}{T_{pu}} - \frac{1}{T} \right]
\]

\[
\ln \gamma_{ibu} = \ln \gamma_{ibu}^C + \ln \gamma_{ibu}^R
\]

\[
n_{i,k} = \sum_{\nu \in S} v_{i,k} y_{i,s}, \quad i = c_1, c_2, c_3, \quad k \in K
\]

\[
q_i = \sum_{\nu \in S} q_i y_{i,s}, \quad i = c_1, c_2, c_3
\]

\[
r_i = \sum_{\nu \in S} r_i y_{i,s}, \quad i = c_1, c_2, c_3
\]

select exactly 3 solvent molecules:

\[
\sum_{\nu \in S} y_{i,s} = 1, \quad i = c_1, c_2, c_3
\]

logic relations:

select each candidate solvent at most once:

\[
\sum_{\nu \in S} y_{i,s} \leq 1, \quad s \in S; \quad I = \{c_1, c_2, c_3\}
\]

solvent ordering:

\[
y_{c_1,s} + y_{c_2,s'} \leq 1
\]

\[
y_{c_1,s} + y_{c_3,s'} \leq 1
\]

\[
y_{c_2,s} + y_{c_3,s'} \leq 1
\]

\[
\forall s' < s; \quad s = 2, \ldots, 9; \quad s' = 1, \ldots, s
\]

0.001 \leq x_{ibu} \leq 0.01, \quad y_{i,s} \in \{0, 1\}, \quad i \in I; \quad s \in S

(R-BM1)

**General problem (N_{max} = 3)**

\[
\max x_{ibu}
\]

subject to

\[
\ln x_{ibu} + \ln \gamma_{ibu} = \frac{\Delta H_{ibu}}{R} \left[ \frac{1}{T_{pu}} - \frac{1}{T} \right]
\]

\[
\ln \gamma_{ibu} = \ln \gamma_{ibu}^C + \ln \gamma_{ibu}^R
\]

\[
n_{i,k} = \sum_{\nu \in S} v_{i,k} y_{i,s}, \quad i = c_1, c_2, c_3, \quad k \in K
\]

\[
q_i = \sum_{\nu \in S} q_i y_{i,s}, \quad i = c_1, c_2, c_3
\]

\[
r_i = \sum_{\nu \in S} r_i y_{i,s}, \quad i = c_1, c_2, c_3
\]

\[
\begin{aligned}
\sum_{\nu \in S} y_{i,s} &= 1, \quad i = c_1, c_2, c_3 \\
\sum_{\nu \in S} x_{ibu} &= 1 \\
\end{aligned}
\]

select only one disjunction:

\[
\sum_{n=1}^{3} \tilde{y}_n = 1
\]

select exactly one solvent for the first designed component:

\[
\sum_{\nu \in S} y_{i,s} \leq 1, \quad i = c_2, c_3
\]

logic relations:

select at most 2 more solvents:

\[
\sum_{\nu \in S} y_{i,s} \leq 1, \quad i = c_2, c_3
\]

select each candidate solvent at most once:

\[
\sum_{\nu \in S} y_{i,s} \leq 1, \quad s \in S; \quad I = \{c_1, c_2, c_3\}
\]

solvent ordering:

\[
y_{c_1,s} + y_{c_2,s'} \leq 1
\]

\[
y_{c_1,s} + y_{c_3,s'} \leq 1
\]

\[
y_{c_2,s} + y_{c_3,s'} \leq 1
\]

\[
\forall s' < s; \quad s = 2, \ldots, 9; \quad s' = 1, \ldots, s
\]

using \(\tilde{y}_n\) to control \(y_{i,s}:\)

\[
\tilde{y}_1 + y_{i,s} \leq 1, \quad s \in S, \quad i = c_2, c_3
\]

\[
\tilde{y}_2 + y_{i,s} \leq 1, \quad s \in S, \quad i = c_3
\]

\[
\tilde{y}_3 \leq \sum_{\nu \in S} y_{i,s}, \quad i = c_2, c_3
\]

\[
\begin{aligned}
\text{reformulation of the disjunctive constraints via big-M:}
0.001(1 - \tilde{y}_1) &\leq x_{c_1} \leq 0.999(1 - \tilde{y}_1) \\
0.001y_3 &\leq x_{c_3} \leq 0.999y_3 \\
0.001 &\leq x_{ibu}, x_{c_1} \leq 1 \\
0 &\leq x_{c_2} - x_{c_1} \leq 1, \quad y_{i,s}, \tilde{y}_n \in \{0, 1\}, \quad i \in I; \quad s \in S; \quad n \in N
\end{aligned}
\]
Disjunctions for Number of Components in the Mixture for Task 2

General problem ($N_{max} = 3$)

\[
\begin{align*}
