LOCAL HEAT TRANSFER FOR WATER IN ENTRANCE REGIONS OF TUBES WITH TAPERED FLOW AREAS AND NONUNIFORM HEAT FLUXES by Nick J. Sekas and James R. Stone Lewis Research Center

.

SUMMARY

Local convective heat-transfer coefficients for water flowing through electrically heated circular tubes with axially varying heat fluxes and flow areas were investigated. Data were obtained in the turbulent flow regime with local Reynolds numbers from 8000 to 50 000 over a Prandtl number range of 1.6 to 4.5. Measurements of mass flow rate, heat flux, water bulk temperatures at tube inlet and outlet, and axial temperature distribution for each run were made and are presented in tabular form. Plots of local to fully developed Nusselt number ratio as a function of heated length-to-diameter ratio are presented. These data are compared with calculated values of the local to fully developed Nusselt number ratios based on a previously reported correlation of entrance effects with tubes of constant flow area and uniform heat flux. The calculated Nusselt number ratios generally approximated the present experimental results.

INTRODUCTION

A knowledge of the variation in local heat-transfer coefficients for liquids flowing in tubes of nonuniform cross-sectional flow area and nonuniform heat flux is directly applicable in the design of fluid-cooling channels for rocket nozzles. Tube-and-shell type heat exchangers and boilers could also conceivably benefit by the use of nonuniform cross-sectional area tubes.

Experimental heat-transfer data are presented in reference 1 for water flowing in constant-flow-area, uniform-heat-flux tubes that had several short unheated lengths preceding the heated portions. Reference 1 also contains a review of other investigations of heat-transfer coefficients in the entrance regions of tubes. However, limited experimental data have been published on the variation with length of local turbulent heattransfer coefficient of liquids in entrance regions of heated tubes with square-edged inlets. Especially lacking are data for tubes with nonuniform cross-sectional flow area, nonuniform heat flux, or both. The investigation described herein was initiated to obtain such data.

Two test sections were used in the present study. The first consisted of a modified section of stainless steel tubing used for cooling an experimental rocket engine, and the second was a chemically milled tapered wall Inconel tube. The first test section had a tapered cross-sectional flow area with a nonuniform heat flux. The flow area increased in the direction of decreasing heat flux. The total length of this test section was $53\frac{1}{8}$ inches (135 cm). The inside diameter varied linearly from 0.380 to 0.844 inch (9.6 to 21.4 mm). The heat flux ratio over the entire length was approximately 16 to 1 because of the tube and wall thickness taper.

The second test section had a constant internal flow area with a diameter of 0.431 inch (10.9 mm) and a tapered wall thickness. The total length of this test section was 43 inches (109.2 cm). The heat flux ratio over the entire length was 2 to 1. The two test sections were reversible and were tested in both directions of flow.

The ranges of conditions investigated in this report were as follows:

Mass flow rate, lb/hr (kg/sec)	370 to 2000 (0.047 to 0.252)
Heat flux, $(Btu/hr)/ft^2(W/m^2)$	0 to 6. 5×10^5 (0 to 2. 05×10^6)
Local bulk temperature, ${}^{O}F({}^{O}K)$	100 to 250 (310 to 395)
Reynolds number	8000 to 50 000
Prandtl number	1.6 to 4.5

APPARATUS

The experimental data were obtained with the test equipment described in detail in reference 2 and shown schematically in figure 1. The flow system is a closed loop in which the water is recirculated by a gear pump. The major components of the loop consist of a resistance-heated stainless steel preheater, a resistance-heated test section, and a water-cooled heat exchanger. The loop is pressurized at a surge tank which is connected to the loop at the pump inlet. The power for heating the test section and the preheater is supplied by two separate saturable core reactors and transformers.

Two test sections were studied in this investigation. The first section, shown schematically in figure 2, was obtained from tubing used to cool an experimental rocket engine. It was fabricated of type 304 stainless steel. The total length of the test section was $53\frac{1}{8}$ inches (135 cm), of which $52\frac{1}{4}$ inches (132.7 cm) was considered as the heated length. The inside diameter varied linearly from 0.380 to 0.844 inch (9.6 to 21.4 mm). The outside diameter varied linearly from 0.410 to 0.940 inch (10.4 to 23.9 mm). The cross-sectional flow area ratio and the heat flux ratio for the entire length of the test section were approximately 1 to 5 and 16 to 1, respectively.

.

The second test section had a constant internal flow area with a tapered wall thickness and was fabricated from 1/2-inch (12.7 mm) diameter Inconel tubing. The inside diameter was 0.431 inch (10.9 mm). The outside diameter was chemically milled to vary linearly from 0.464 to 0.500 inch (11.8 to 12.7 mm). The heat flux ratio over the entire length of this section was 2 to 1. The total heated length was 43 inches (109.2 cm). Copper bus bars were attached to both ends of the test sections for applying electrical power.

The system flow rates were measured by a turbine-type flowmeter. The flowmeter output was read from a frequency converter and checked with a counter. The system pressure was measured by a bourdon tube gage connected at the pump inlet. Chromel-Alumel thermocouples were spotwelded to the outer wall of the test sections at the same circumferential position for all axial temperature measurements. Inlet and outlet bulk temperatures were measured by thermocouples in the liquid stream at the inlet and outlet plenums. All the temperatures were recorded on self-balancing potentiometers. The ac power to the test section was measured by a dynamometer-type wattmeter. The voltage drop across the test section was measured by a vacuum tube voltmeter.

PROCEDURE

Each day before data were taken, water was circulated and boiled in the test section. Noncondensable gases were vented from the system through a line connected to the high point of the loop. Dissolved gas content was maintained at less than 3 ppm by weight based on the average molecular weight of air.

In order to check the thermocouples, runs were made in which heat was applied to the preheater only. Since the heat losses from the test section to the surrounding environment were small, the tube outer wall temperatures could be checked for consistency against the water bulk temperatures at the inlet and outlet plenums. This was done over the range of bulk temperatures encountered by adjusting the preheater power. The temperature recording instruments were calibrated before and after each series of runs.

The conditions for each run were established by adjusting the power to the preheater and test section, thus setting the inlet and outlet bulk temperatures, for preselected values of flow rate. When the inlet and outlet bulk temperatures became constant with time, the data for that run were taken. The system surge tank pressure was maintained at 120 psig (828 kN/m²).

DATA REDUCTION

The current through the test section was computed from the wattmeter and corresponding voltmeter readings. The local heat flux at the inside wall of the test section was calculated from the following equation:

q = 3.413
$$\frac{I^2 \alpha}{\pi D_i A_w}$$
, $\frac{Btu}{(hr)(ft^2)}$

or

$$q = \frac{I^2 \alpha}{\pi D_i A_w}, \qquad \frac{W}{m^2}$$

where

I current through test section, A

 α electrical resistivity, ohm-ft (ohm-m)

D_i local inside diameter, ft (m)

 A_w local wall cross-sectional area, ft² (m²)

The total resistance of the first test section was measured at 70° and 230° F (294^o and 383° K). The values obtained were 0.0299 ohm and 0.0333 ohm, respectively. These values of total resistance were substituted in the electrical resistivity equation

$$\alpha = \frac{R}{\int \frac{dx}{A_w}}$$

where R is total test section resistance in ohms and dx is incremental test section length in feet (m), to obtain the resistivity equation as a function of temperature

where T is temperature, ${}^{O}F$. A similar expression was determined for the second test section. When the local heat flux was calculated, the local resistivity based on the local outside wall temperature was used.

The local outside wall temperatures were obtained from the axially located thermocouples by means of the curve of calibrated electromotive force against temperature for Chromel-Alumel thermocouples. The inside wall temperature was computed as in reference 2, considering internal heat generation and no axial heat flow. The thermal conductivity of the stainless steel test section was obtained from reference 3, and that for Inconel from reference 2.

The values of local Nusselt, Reynolds, and Prandtl numbers were computed on the basis of the physical properties of water evaluated at the local bulk temperatures. The water local bulk temperatures were obtained by a heat balance. The physical properties of water were obtained from reference 4.

The local fully developed Nusselt number to which measured values were ratioed was computed from the local values of Reynolds and Prandtl numbers by the following relation obtained from reference 1 as an approximation for Prandtl numbers from 1.5 to 8:

$$Nu_{fd} = 0.023 (Re)^{0.8} (Pr)^{0.47}$$

where

•

Nu_{fd} local fully developed Nusselt number

Re local Reynolds number

Pr local Prandtl number

The calculated local Nusselt number ratio of reference 1 with which the experimental ratios were compared was obtained by the following equation, which was for the case of constant flow area and uniform heat flux:

$$\frac{\text{Nu}}{\text{Nu}_{\text{fd}}} = 1 + \frac{2.3}{0.5 \text{ } \text{z}^2 + \text{z} + \text{z}^{1/4}} \text{ Re} \ge 8000$$

where

$$z = \frac{\sqrt{xy}}{D_i Pr^{0.4}} \sqrt{\frac{1}{1 + 0.01 \text{ y}/D_i Pr^{0.4}}}$$

z distance and physical properties parameter

x heated length to local point of test section (see fig. 2)

y total length to local point of test section (see fig. 2)

RESULTS AND DISCUSSION

The experimental data for the tapered-flow-area, nonuniform-heat-flux test section are presented in table I. The data for the constant-flow-area, tapered-heat-flux test section are presented in table II. These tables contain the local heat flux and outside wall temperatures, as well as calculated inside wall and bulk temperatures, and local Prandtl, Reynolds, and Nusselt numbers.

A plot of Nu/Nu_{fd} against the ratio of length from the start of heating to local diameter for the tapered-cross-sectional-flow-area test section is presented in figure 3. The lower curve represents the experimental data for the diverging flow area case and the upper curve for the converging flow area. Also presented are the calculated curves for both cases. These calculated curves were obtained using the distance and physical property parameter z of reference 1. The curves shown are faired through the calculated points for all the data runs in their respective directions of flow. It can be seen from the data that the converging flow (and increasing flux) case gives a slightly higher Nusselt number ratio than the diverging flow case at the same x/D ratio for ratios less than 10. This trend is shown by the calculated results, to a smaller degree. In both cases the experimental Nusselt number ratio exceeds the calculated.

The Nusselt number ratio is plotted against the length-to-diameter ratio for the constant-flow-area, tapered-flux test section in figure 4. Figure 4(a) presents the data for decreasing heat flux in the direction of flow and figure 4(b) the data for increasing heat flux. The respective faired calculated curves using the z parameter correlation. are also plotted. Although a small effect of Prandtl number on the Nusselt number ratio does exist, it was not presented because of the limited data taken and is not of magnitude to significantly affect the results presented herein. The experimental results can be approximated in both cases by the z parameter correlation

SUMMARY OF RESULTS

The present investigation has shown that the distance and physical properties parameter of NASA TN D-3098 can be used to approximate the local Nusselt number ratio near the entrances of tubes with tapered flow areas and nonuniform heat fluxes, over the range of conditions tested.

The ratio of local to fully developed Nusselt number is slightly greater for converging flow area and increasing heat flux than for the opposite case at the same ratio of heated distance to local diameter near the inlet of the test section studied. For the range of conditions tested the effect of flow direction on heat transfer was slightly more pronounced for the nonuniform-flow-area, nonuniform-heat-flux test section than for the nonuniform-heat-flux, constant-flow-area test section.

TAPERED-HEAT-FLUX TEST SECTION

Figure 2. - Tapered tube test section. Flow can be reversed, so that inlet becomes outlet. Dimensions are in inches (cm).

Figure 3. - Variation in Nusselt number ratio with length to local diameter ratio from start of heating for tapered-cross-sectional flow-area test section.

Figure 4. - Variation in Nusselt number ratio with length to local diameter ratio from start of heating for constant-flow-area test section.

If Undeliverable (Section 158 Postal Manual) Do Not Return

"The aeronautical and space activities of the United States shall be conducted so as to contribute . . . to the expansion of human knowledge of phenomena in the atmosphere and space. The Administration shall provide for the widest practicable and appropriate dissemination of information concerning its activities and the results thereof."

-NATIONAL AERONAUTICS AND SPACE ACT OF 1958

NASA SCIENTIFIC AND TECHNICAL PUBLICATIONS

TECHNICAL REPORTS: Scientific and technical information considered important, complete, and a lasting contribution to existing knowledge.

TECHNICAL NOTES: Information less broad in scope but nevertheless of importance as a contribution to existing knowledge.

TECHNICAL MEMORANDUMS: Information receiving limited distribution because of preliminary data, security classification, or other reasons.

CONTRACTOR REPORTS: Scientific and technical information generated under a NASA contract or grant and considered an important contribution to existing knowledge.

TECHNICAL TRANSLATIONS: Information published in a foreign language considered to merit NASA distribution in English.

SPECIAL PUBLICATIONS: Information derived from or of value to NASA activities. Publications include conference proceedings, monographs, data compilations, handbooks, sourcebooks, and special bibliographies.

TECHNOLOGY UTILIZATION PUBLICATIONS: Information on technology used by NASA that may be of particular interest in commercial and other non-aerospace applications. Publications include Tech Briefs, Technology Utilization Reports and Notes, and Technology Surveys.

Details on the availability of these publications may be obtained from:
