Korea University Guro Hospital, Seoul, Korea (Republic of)

**Background:** Heart failure is known to be associated with increased adverse clinical outcomes in coronary artery diseases. The impact of percutaneous coronary intervention (PCI) for chronic total occlusion (CTO) in patients (pts) with new onset heart failure is not clear. We compared the 12-month clinical outcomes of pts treated by PCI with optimal medical therapy (OMT) for CTO lesions in pts with new onset heart failure (pts)

**Methods:** A total of 458 consecutive CTO pts newly diagnosed with heart failure or showing symptoms of heart failure (NYHA ≥ 2 or CCS ≥ 2 class 2) were divided into 2 groups; one group underwent PCI (PCI group; n = 246) and the other group was treated with OMT (OMT group; n = 212). Major clinical outcomes were compared between the two groups up to 12 months.

**Results:** At baseline, the OMT group had a higher prevalence of elderly, cerebro-vascular accidents, de novo lesion, left main disease, multivessel disease, multivessel CTO, RCA-CTO, and abundant collaterals (≥ grade 2), whereas the PCI group had a higher prevalence of male gender, prior MI, prior PTCA and LAD-CTO lesions. Clinical outcomes at 12 months were similar between the 2 groups except lower 12-month mortality in the PCI group (Table). After baseline adjustment by multivariate analysis, however, there was no difference between the 2 groups.

**Conclusion:** In our study, mechanical recanalization by PCI for CTO lesions in pts with new onset heart failure as compared with OMT seems to have no benefit in reducing 12-month mortality. Long-term follow up with a larger study population will be necessary for further determination.

**Comparison in Cardiac Remodeling Between Surgical Treatment and Device Closure of Atrial Septal Defect**

Yoo-Mi Hwang, Ji Hoon Kim, Keom Woong Moon, Ki Dong Yoo, Chul-Min Kim, Mi-hyang Jung, Soo-yeon Jung, Ghee-Hee Kim

St. Vincent's Hospital, Suwon, Korea (Republic of)

**Background:** Atrial septal defect (ASD) is the 2nd most common congenital heart anomaly in adults. As treatment options, there are operative ASD closure (Surgery) and percutaneous device closure (Device). The aim of this study was to elucidate the cardiac remodeling after ASD closure and to compare the effects of Surgery and Device in similar ASD size.

**Methods:** Among patients who underwent ASD closure in Catholic medical school, St. Vincent’s Hospital from January 2004 to December 2012, 28 patients were enrolled. Transesophageal echocardiography (TEE) was performed before and after correction of the ASD in both Surgery and Device groups.

**Results:** Although there were significant differences in age and ASD size in both groups, after closing ASD, LV dimension increased in both groups, on the other hand, decrease in right atrium volume (RAVol) and maximum regurgitation velocity of tricuspid valve (TR Vmax) was noted. Aortic diameter and LV ejection fraction increased in Surgery group. Further subgroup analysis with ASD size of 13 to 24mm was analyzed to compare differences in cardiac remodeling between the two groups. There were coherent results of increase of LV dimension and reduction of TR Vmax and RAVol in both subgroups. However, RAVol reduction was more remarkable in Surgery than Device subgroup.

**Conclusion:** Although there was difference in baseline parameters between two groups, which may have affected the choice of treatment option, the parameters measured by TEE showed significant change in structural cardiac remodeling. By subgroup analysis regarding to ASD size, showed consistent improvements in cardiac geometry without significant difference between the groups. In conclusion, in selected cases of ASD, it is reasonable to treat percutaneously considering complication occurrence, post-procedural recovery, and hospital stay.

**Angiographic Characteristics and Clinical Outcomes of the Use of Dual Therapy Stent**

Jung Min Fam1, Reni Cai Zuan Lim1, Yee How Lau2, Key Woon Ho1, Chee Tang Chiu1, Paul Toon Lim Chiam1, Khung Keong Yeo3, Jack Wei Chieh Tan1, Soo Tek Lim1, Tian Hoi Koh1, Aaron Sung Lung Wong2

1National Heart Centre Singapore, Singapore, Singapore, 2Singapore Cardiac Data Bank, Singapore, Singapore

**Background:** A novel dual therapy stent (DTS) may improve clinical outcome due to a combination of sirolimus drug elution and endothelial progenitor cell technology for reduced restenosis and accelerated endothelialisation. However clinical data remains limited on the use of this novel technology. We aim to report on the use of a novel DTS device in our centre.

**Methods:** All patients who underwent PCI with the Combo® DTS in our centre were enrolled. All patients underwent diagnostic angiograms and PCI according to guideline recommended indications and techniques. Baseline clinical and angiographic characteristics were collected. Clinical outcomes for MACCE at 6 and 12 months were studied.

**Results:** Fifty three patients (83% male) of mean age 61.42 +/- 11.63 years were studied. 15.1% (n= 8), 24.5% (n= 13) and 60.4% (n= 32) were admitted for STEMI, ACS and Stable angina respectively. The prevalence of hypertension, hyperlipidaemia and diabetes mellitus were 88.7% (n=47), 75.5% (n=40) and 59.0% (n=27) respectively. 12.7% (n= 7) had left main disease and 41.8% (n= 23) had triple vessel disease. 69 Combo® DTS with a mean diameter of 3.06 +/- 0.35 mm and a mean length of 22.07 +/- 5.55 mm were implanted. 50.9% (n= 20) were implanted in the LAD, LCx and RCA respectively. 4.3% (n= 3) were deployed in the left main artery and in bypass grafts respectively. There were 10.1% (n=9), 69.6% (n=48) and 20.3% (n=14) ACC/AHA angiographic type A, B and C lesions. 6 (8.7%) and 7 (10.1%) were CTO and bifurcation lesions respectively. Angiographic success rate was 100%. There were no cases of stent thrombosis or inhospital mortality.

**Conclusion:** The use of Combo® DTS was associated with excellent angiographic and short term clinical outcome in this study. We plan to report on 6 month clinical outcomes at the time of presentation.

**Bioabsorbable Vascular Scaffolds (BVS) Eluting with Everolimus: for Percutaneous Coronary Intervention (PCI) of Patients with De-novo Coronary Artery Lesion: Our Experiences at Apollo Hospitals Dhaka**

Shams Munwar, Ahm Walid Islam, Shahbuddin Talukder, A. Q. M. Reza, Tameez Ahmed, Aftar H. Bhuiyan, Rowshan Masud, Atique B. Siddique

Apollo Hospitals Dhaka, Dhaka, Bangladesh

**Background:** Aim of the study was to evaluate the primary procedural success of percutaneous coronary intervention (PCI) of de-novo coronary artery lesion by using BVS Absorb stents eluting with Everolimus.

**Methods:** Total 16 patients were enrolled in this very preliminary study of BVS absorb. Among them, Male: 11 and Female: 5. Total 20 stents were deployed. Mean age were for Male: 56 yrs, for Female: 60 yrs. Associated CAD risk factors were Dyslipidemia, High Blood pressure, Diabetes Mellitus, Positive FH for CAD and Smoking (male).

**Results:** Among the study group; 13 (81%) were Dyslipidemic, 10(62.5%) were hypertensive; 6 (37.5%) patients were Diabetic, FH 3(18.75%), and 2(18%) were all male smoker. Female patients were more obese (BMI M 25: F 27) and developed CAD in advance age. A common stented territory was for LAD: 6 (37.5%), LCx 5 (25%), RCA 6(37.5%). One patient had both LCx and LAD stenting. Total 3 patients had double/overlapping stent in RCA lesion. Territory wise distributions of BVS Absorb stent were for LAD 6(30%), RCA 9 (45%), and LCx 5 (25%).
