Keywords: Fluidized bed drying Lactobacillus lactis Prediction model Probiotic Protective agents

ABSTRACT

In the present study, Lactobacillus lactis 1464 was attempted to be incorporated in shrimp feed pellets. The fresh culture (25% volume per weight) with and without pH adjustment was mixed into feed ingredients prior to the pelleting process at ambient temperature. The wet pellets were dried using a fluidized bed dryer at 50 °C, 60 °C, 70 °C and 80 °C to achieve a moisture content below 11%. The results indicated that the strain viability depended on the drying temperature with a viable cell number of approximately $10^6 - 10^8$ CFU/g and the pH of the culture was found to affect the strain viability during drying. At all drying temperatures, the strain survival after drying ranged from 75.94% to 92.28% at pH 3.8 and from 89.54% to 96.87% at pH 7.0. Moreover, the addition of protectants was found to enhance the strain survival during drying. In particular, milk powder and monosodium glutamate (MSG) exhibited significant ($p < 0.05$) protective effect on the viability at a high temperature of 80 °C. During storage at 30 \degree C, a high survival rate was found for the strain with MSG and acacia gum. Furthermore, the prediction model for long-term storage stability of the strain was found to validate only at a low temperature of 4 \degree C, in comparison to a high temperature of 30 \degree C.

Introduction

Nowadays, probiotics offer a promising alternative approach for controlling shrimp diseases and improving shrimp health through their potential to control pathogens, to stimulate the immune response, to improve water quality and to enhance nutrition through the production of digestive enzymes [\(Verschuere et al.,](#page-6-0) [2000; Gullian et al., 2004; Wang, 2007](#page-6-0)). To achieve health benefits, probiotic bacteria must be viable and available at high con-centration, typically 10⁶–10⁷ CFU/g of product ([Kosin and Rakshit,](#page-5-0) [2006\)](#page-5-0). Furthermore, incorporation into feed pellets is more effective in conveying probiotics into animals compared to direct application into rearing systems. It is also applicable for intensive aquaculture and requires no additional labor or shrimp handling ([G](#page-5-0)ó[mez et al., 2007](#page-5-0)). The viability and stability of probiotics have been a technological challenge in feed manufacturing because probiotics, including Lactobacillus, Bacillus and yeast, are

susceptible to the high temperature of the pelleting and drying process. According to [Biourge et al. \(1998\)](#page-5-0), Bacillus CIP5832 spores in dog diet were found to have in excess of 99% loss after the extrusion, expansion and drying processes. Furthermore, the viable count of yeast in shrimp feed pellet decreased by 10^5 fold after extruding through a meat grinder at $72 °C$ for 31 s followed by drying at 65 °C for 6 h (Aguirre-Guzmán et al., 2002).

Fluidized bed drying is extensively used for drying wet particulate and granular materials. In a fluidized bed dryer, the probiotic cell suspension is mixed with a vibrating bed of absorbers or matrix molecules which helps to form capsules by adherence ([Nag and Das,](#page-6-0) [2013](#page-6-0)). This process is comparatively economical. It involves low energy consumption, high throughput and imparts moderate heat stress to the bacterial cells [\(Beker and Rapoport, 1987; Nag and Das,](#page-5-0) [2013](#page-5-0)). Furthermore, this process was successfully used for the preparation of dried granules or powders containing lactic acid bacteria [\(Santivarangkna et al., 2007; Nag and Das, 2013](#page-6-0)). According to [Nag and Das \(2013\)](#page-6-0), fluidized bed drying was able to retain viability of Lactobacillus casei CRL 431 of more than 7.7 log CFU/g during storage at 25 °C for 12 wk. Mille et al. (2004) revealed that the Lactobacillus plantarum viability in casein powder was up to 80% after Example of the dring partial dring in Casembower at Specific at 35 C for 30 min. Correspondingly, the the mail address: faginkw@ku.ac th (P. Wanchaitanawong) **Example 200 min.** Corresponding Example 200 min. Correspondingl

survival of *Lactobacillus brevis* in fish feed was 99% (10 $^8-10^9$ CFU/g) after fluidized bed drying at 40 \degree C for 40–60 min with a moisture content of 5% [\(Toledo et al., 2010\)](#page-6-0). Several studies have reported that the viability of lactic acid bacteria during drying and storage was enhanced by the addition of protective agents such as trehalose, skim milk, whey protein, soy protein isolate, monosodium glutamate, sucrose, lactose, sorbitol and polymers such as carboxymethyl cellulose, dextran and acacia gum ([Morgan et al., 2006; Santivarangkna](#page-6-0) [et al., 2007; Golowczyc et al., 2011; Lapsiri et al., 2013](#page-6-0)). In the present study, an overnight culture of Lactobacillus lactis 1464 was incorporated into shrimp feed pellets prior to the pelleting process at ambient temperature and dried in a fluidized bed dryer to achieve a moisture content lower than 11%. The effect of the drying temperature, culture pH and protectants on the strain survival during drying was determined. Additionally, the storage stability of the strain in the pellets at 4 \degree C and 30 \degree C was also evaluated.

Materials and methods

Preparation of soymilk medium

Soymilk medium was prepared as described by [Wang et al.](#page-6-0) [\(2002\)](#page-6-0). Soybeans were washed and soaked overnight in distilled water. The soaked soybeans were blended with distilled water (soybean:water = 1:10 w/v) for 3 min and then filtered through a double-layer cheesecloth to obtain soymilk. 1% (w/v) glucose (Ajax Finechem; Taren Point, NSW, Australia) was added into the soymilk before sterilization at 121 \degree C for 15 min.

Microorganism

L. lactis 1464 isolated from the sediment of a Nile tilapia fish pond with antimicrobial activity against shrimp pathogen was obtained from the Department of Biotechnology, Kasetsart University, Thailand. After two successive transfers of the strain in de Man, Rogosa and Sharpe (MRS) broth (Merck; Darmstadt, Germany) at 37 \degree C for 24 h, the activated culture was again inoculated into MRS broth at 37 \degree C for 24 h which served as the inoculum ([Lapsiri et al., 2011](#page-6-0)). The overnight cultures were conducted in 250 mL Erlenmeyer flasks containing 120 mL of sterile soymilk and inoculated with 5 mL of the inoculum (approximately 10^9 CFU/mL). The sample was incubated at 37 \degree C for 24 h.

Preparation of shrimp feed pellets

The formulated shrimp feed consisted of 40% fish meal, 8% shrimp head meal, 20% rice bran, 10% wheat flour, 5% sago flour, 10% horse tamarind leaves powder, 5% soybean oil and 2% premix by weight. The feed mixture was sterilized at 121 \degree C for 30 min and dried overnight in a hot air oven (Memmert GmbH; Memmert, Germany) at 55 °C. Gelatin (3% w/v) as a feed binder was mixed with the dried mixture in a stand mixer. The overnight culture (25% v/w) of *L. lactis* 1464 with and without pH adjustment to 7.0 with 5 M NaOH (Ajax Finechem; Taren Point, NSW, Australia) was then added. After mixing for 3 min, soybean oil was then added and mixed for 3 min again. The feed mixture was pressed into pellets at ambient temperature using a laboratory pellet mill with a 2 mm diameter (California Pellet Mill Co.; Crawfordsville, IN, USA). The wet pellets (250 g) were dried in a laboratory fluidized bed dryer (Sherwood Scientific; Cambridge, UK) with a 5 L stainless chamber at various air inlet temperatures—50 °C, 60 °C, 70 °C and 80 °C. The fluidizing air flow velocity was held constant at 3.10 m/s. Samples were collected during drying to determine the viability of L. lactis 1464 and the moisture content. The specific rate of degradation (k) of L. lactis 1464 during drying at constant temperature was calculated as described by first-order kinetics as shown in Equation (1) [\(Desmond et al., 1998](#page-5-0)).

$$
\log N = \log N_0 - kt \tag{1}
$$

where N_0 is the number of initial viable cells and N is the number of viable cells at any time both expressed in colony forming units (CFU) per gram, k is the specific rate of degradation per minute and t is the drying time in minutes. A plot of the term of log N versus time (t) yields the estimate of k from the slope.

Effect of protective agents on viability of L. lactis 1464 after fluidized bed drying

Each protective agent $(5\% w/v)$ including, monosodium glutamate (MSG) (Ajinomoto; Bangkok, Thailand), milk powder (Dumex; Samut Prakan, Thailand), acacia gum (MT Instrument; Bangkok, Thailand), maltodextrin (Du Zhi Xue, China) was added into the overnight cultures of L. lactis 1464 prior to mix with the feed mixture. The shrimp feed pellets were prepared by the same manner as described in the preparation of the shrimp feed pellets. The wet pellets with an initial moisture content of approximately 26.5% were dried at various temperatures (50 \degree C, 60 \degree C, 70 \degree C and 80 \degree C) until the moisture content was below 11%.

Storage of dried shrimp feed pellets

Dried shrimp feed pellets (5 g) were placed into plastic zip bags and kept at 4 \degree C and 30 \degree C for 6 mth. The viable cell counts were determined every month. Each treatment was duplicated.

Accelerated storage test

Dried shrimp feed pellets were incubated in a hot air oven at 50 °C, 60 °C, 70 °C and 80 °C. At 50 °C, samples were taken after 24 h, 48 h, 72 h, 96 h and 120 h of exposure; at 60 °C, after 3 h, 6 h, 9 h, 12 h, 15 h and 18 h; and at 70 $^{\circ}$ C and 80 $^{\circ}$ C after 1 h, 2 h, 3 h, 4 h, 5 h and 6 h to determine the residue viable counts. The specific rate of degradation (k) was calculated.

Enumeration viable counts

Viable counts were enumerated using a pour plate technique. The sample of feed pellets (5 g) was rehydrated with 45 mL of sterile 0.85% NaCl (Ajax Finechem; Taren Point, NSW, Australia) to obtain 1:10 dilution and mixed in a stomacher (Seward Laboratory Systems Inc; Davie, FL, USA) for 1 min. Serial dilutions were made for each sample and plated on MRS agar containing 0.03% bromocresol purple (Ajax Finechem; Taren Point, NSW, Australia). Plates were incubated at 37 \degree C for 24 h and enumerated for colony forming unit per gram (CFU/g). Each treatment was duplicated. The survival rates were calculated as: Survival rate $(\%) = (\log N / \log N_0) \times 100$, where N₀ is the number of initial viable cells and N is the number of viable cells at any time both expressed in CFU per gram ([Reddy et al., 2009](#page-6-0)).

Moisture content

The moisture content of the feed pellets was determined according to the relevant international standard 6496 ([International](#page-5-0) [Standard Organization, 1999\)](#page-5-0).

Statistical analysis

All experiments were carried out in duplicate. The data were statistically analyzed for analysis of variance in a completely randomized design. Significant divergences among mean values were established using Duncan's multiple range tests at the 95% confidence interval. All statistical analyses were performed using the SPSS Software version 12 (SPSS Inc., White Plains, NY, USA).

Results and discussion

Effect of temperatures and pH on the viability of L. lactis 1464 during fluidized bed drying

The fresh culture of L. lactis 1464 with and without pH adjustment was added into shrimp feed pellets and subjected to drying using a fluidized bed dryer to prevent deterioration over long term storage. The viability loss of the strain at pH 3.8 and pH 7.0 in shrimp feed pellets and the moisture content during the fluidized bed drying at various temperatures are shown in Fig. 1A and B. It was observed that the moisture content decreased gradually from approximately 26.5% to below 11% after drying at 50 \degree C for 15 min, 60 °C for 10 min, 70 °C for 5 min and 80 °C for 5 min. It was clear that higher temperatures resulted in a shorter time to reach the equilibrium moisture content. However, it affected the viability of the strain which decreased as the temperature increased. At pH 3.8, a cell reduction of only 0.57 log CFU/g and 0.94 log CFU/g with survival rates of 92.28% and 87.38%, respectively, ([Table 1](#page-3-0)) were obtained during drying at 50 \degree C and 60 \degree C, respectively, while a high cell reduction of 1.63 log CFU/g and 1.80 log CFU/g with survival rates of 78.16% and 75.94%, respectively, were observed after drying at 70 °C and 80 °C, respectively. It is known that temperature is the important factor affecting the viability of probiotics during drying process (Chávez and Ledeboer, 2007). The viability loss was mainly due to the damage to the cell membrane and proteins ([Ananta et al., 2005\)](#page-5-0). [Wang et al. \(2004\)](#page-6-0) reported that the numbers of bifidobacteria and other lactic acid bacteria decreased with increasing outlet air temperature in spray drying. A similar finding was reported by [Bayrock and Ingledew \(1997\)](#page-5-0) for fluidized bed dried Saccharomyces cerevisiae. Additionally, the decrease in viable cell depends not only on the drying temperature but also on the time of exposure to heat (Chávez and Ledeboer, 2007). Hence, the drying time for biomaterial preservation should be as short as possible. In the current study, the wet pellets of probiotic shrimp feed were dried to achieve a moisture content below 11% and to maintain a high viable cell count (above 10^6 CFU/g) which was recommended for animal feed [\(Uppal et al., 2008\)](#page-6-0). Therefore, drying times of 15 min, 10 min, 5 min and 5 min was sufficient for

fluidized bed drying of shrimp feed pellets at 50 °C, 60 °C, 70 °C and 80 °C, respectively.

At pH 7.0 (Fig. 1B), a similar trend was also observed; however, the viability of the strain was more stable than at pH 3.8. The survival rate of the strain after drying ranged from 89.54% to 96.87% at all drying temperatures. As shown in [Table 1,](#page-3-0) when heating at low pH, the reduction of the strain decreased faster than at high pH. The specific degradation rate (k) of the strain at pH 3.8 was higher than at pH 7.0 for every drying temperature. Many studies have reported that microorganisms have their maximum heat resistance at a pH value close to neutral (Ocio et al., 1994; López et al., 1996). Corre-spondingly, [Juneja and Eblen \(1999\)](#page-5-0) found that the heat tolerance of bacteria decreased with decreasing pH and decreased even more when presented in high temperatures. Therefore, the strain with the pH adjustment to 7.0 was chosen for further study.

Effect of protective agents on survival of L. lactis 1464 in shrimp feed pellets

In order to enhance the viability of the strain during fluidized bed drying, four protective agents-MSG, acacia gum, milk powder and maltodextrin-were tested for their protective effect against various drying temperatures. As shown in [Table 2](#page-3-0), the survival rate of the strain was related to the type of protective agents. In all treatments, the strain exhibited greater high survival rates of approximately 84%–99% (viable cell number of 10^6 – 10^8 CFU/g) after the drying process. There was no significant difference in survival after drying at 50 °C. In contrast, a significant ($p < 0.05$) effect of protectants was observed during drying at 80 \degree C. Among the four protective agents, MSG showed the highest protective effect on the viability of the strain, followed by milk powder. This was consistent with the report of [Sunny-Roberts and Knorr \(2009\),](#page-6-0) where the survival of spray-dried Lactobacillus rhamnosus increased approximately by 1 log cycle when MSG was added in the drying medium. MSG was able to stabilize the cell membrane via the reaction between its amino group and the carboxyl group of the microorganism proteins [\(Carvalho et al., 2003](#page-5-0)). The results also showed that milk powder exhibited a protective effect against high temperatures. This was probably because milk protein prevented cell injury by coating the cell wall proteins ([Gharsallaoui et al.,](#page-5-0) [2007; Ghandi et al., 2012\)](#page-5-0) and stabilizing the cell membrane constituents [\(Reddy et al., 2009\)](#page-6-0). Moreover, [Silva et al. \(2011\)](#page-6-0) suggested that protein may create a structure which is easy to rehydrate after drying. The macromolecules of protein, such as sodium caseinate,

Fig. 1. Viability loss of L. lactis 1464 at (A) pH 3.8 and (B) pH 7.0 in shrimp feed pellets and moisture content during fluidized bed drying at various temperatures. Viability is shown with solid lines, while short dashed lines show the moisture content.

 a^a k = Specific rate of degradation.

are not capable of passing through the structure of the peptidoglycan layer that covers the cell membrane of lactic acid bacteria ([Ghandi et al., 2012\)](#page-5-0). It is able to form non-interacting osmotically inactive bulking compounds causing spacing amongst cells and not allowing their cell walls to come closer and fuse [\(Oldenhof et al.,](#page-6-0) [2005; Joshi and Thorat, 2011\)](#page-6-0).

Viability of L. lactis 1464 in shrimp feed pellets during storage

In order to determine the shelf-life of L. lactis 1464 in shrimp feed pellets, the dried pellets were kept in plastic zip bags and stored at 4 \degree C and 30 \degree C for 6 mth. As shown in [Fig. 2](#page-4-0), the decline in viable cells is represented by the logarithmic value of the $N/N₀$ for different storage periods. After storage for 6 mth at 4 \degree C, there was no significant ($p > 0.05$) loss of initial viability of fluidized bed dried L. lactis 1464 either with or without protective agents. On the other hand, high mortality was observed in all treatments at the higher storage temperature of 30 $^{\circ}$ C. A similar finding was reported by [Wang et al. \(2004\)](#page-6-0) where the viability of spray-dried Streptococcus thermophilus and Bifidobacterium longum decreased as the storage temperature increased. This was also consistent with [Gardiner et al.](#page-5-0) [\(2002\)](#page-5-0), who reported that the viability of a probiotic was maintained at 10^8 CFU/g during storage at 4 °C, while viable cells declined to 10^6 CFU/g after 49 d when stored at 30 °C.

In addition, it was also observed that the reduction rate of viable cells at 30 \degree C was markedly influenced by the drying temperature. The viability of the strain dried at higher temperature declined faster than at lower temperature. For example, the viability of the strain dried at 50 \degree C [\(Fig. 2A](#page-4-0)) slightly decreased approximately 2-4 log CFU/g (from approximately 10^8 CFU/g to approximately $10^3 - 10^5$ CFU/g) after 6 mth. In contrast to the strain dried at 80 °C, viable cells reduced about $1.5-3$ log CFU/g in 3 mth and decreased rapidly to an undetectable level after 4 mth [\(Fig. 2](#page-4-0)D). A similar trend was found in the pellets dried at 70 $\rm{°C}$ ([Fig. 2](#page-4-0)C). Furthermore, the viability of the strain during storage was enhanced by the addition of protectants. All protectants showed a similar ability to protect cells in the first 3 mth. After 4 mth, acacia gum and MSG exhibited significant protective ability for the strain dried at 50 \degree C and 60° C whereas no significant protective effect on the strain dried at 70 °C and 80 °C was observed. The viability loss during storage was mainly due to the lipid oxidation of the cell membrane ([Teixeira et al., 1996; Santivarangkna et al., 2007](#page-6-0)). Acacia gum and MSG exhibited protective coating on the cell wall and had antioxidant properties which could prevent cell damage due to an oxidation reaction ([Desmond et al., 2002; Sunny-Roberts and](#page-5-0) [Knorr, 2009\)](#page-5-0).

From the results, cell injury and inactivation occur not only during feed processing, but also during storage. The viability of probiotic bacteria during storage is inversely related to the storage temperature [\(Gardiner et al., 2000](#page-5-0)). It is clear that pellets stored at $4 °C$ showed the highest stability over 6 mth. However, refrigeration is inconvenient for the supplier and retailer due to its high cost. Thus, it is a major challenge to produce probiotic products that are stable at ambient temperature. In this study, the viability of the strain dried at 50 \degree C and 60 \degree C with the addition of acacia gum and MSG was maintained at 10^7 CFU/g over 3 mth which could still meet the requirements for the level of viable cells in probiotic products.

Prediction of the storage stability of L. lactis 1464 in shrimp feed pellets

In this study, the accelerated storage test was used to predict the storage stability of the strain in dried feed pellets. The changes of L. lactis 1464 viability in the 70 \degree C-dried pellets with the addition of MSG under storage temperatures of 50 °C, 60 °C, 70 °C and 80 °C are shown in [Fig. 3](#page-4-0) and the slope of each line is equal to the specific degradation rate per hour (k) as shown in [Table 3.](#page-4-0) The correlation between the temperature and the k value can be described by the Arrhenius equation as shown in Equation (2) ([Lee, 1991](#page-6-0)).

$$
k = k_0 e^{(-E_a/RT)} \tag{2}
$$

where R is the universal gas constant (8.32 J/mol.K), E_a is the apparent activation energy in kilojoules per mol, T is the absolute temperature in degrees kelvin and k_0 is the pre-exponential constant. In [Fig. 4,](#page-5-0) when the log k values were plotted against $1/T$, the regression equation was obtained as $log k = 28.048 - 9.4984$ [(1/T) \times 1000] which was used for determination of the k value at 4 \degree C and 30 \degree C

Table 2

Survival of L. lactis 1464 in shrimp feed pellets with various protective agents after fluidized bed drying at various temperatures, not adjusted pH in culture in shrimp feed pellets.

Protective agent	Survival [*] $(\%)$			
	50 °C, 15 min	60 °C. 10 min	70 °C. 5 min	80 \degree C. 5 min

*Values in the same column with different superscripted lowercase letters $(a-e)$ are significantly different using Duncan's multiple range test $(p < 0.05)$. $[†]$ MSG = monosodium glutamate.</sup>

Fig. 2. Viability loss of L. lactis 1464 in feed pellet dried at: (A) 50 °C for 15 min; (B) 60 °C for 10 min; (C) 70 °C for 5 min; (D) 80 °C for 5 min during storage at 4 °C (solid lines) and 30 °C (short dash lines) for 6 mth with various protectants. (●; Control, ▼; MSG, ■; acacia gum, ◆; milk powder, ▲; maltodextrin). MSG = monosodium glutamate.

 $(k_4 = 6 \times 10^{-7}$ /h and $k_{30} = 5 \times 10^{-4}$ /h). Therefore, the prediction models of stability at 4 °C and 30 °C were obtained by replacing the value of N₀ and k_4 or k_{30} in Equation [\(1\),](#page-1-0) as shown in Equations (3) and (4), respectively:

Fig. 3. Viability in the 70 \degree C-dried pellets with the addition of monosodium glutamate stored at various temperatures.

$$
\log N = \log N_0 - 6 \times 10^{-7} t \tag{3}
$$

$$
\log N = \log N_0 - 5 \times 10^{-4} t \tag{4}
$$

To validate Equations (3) and (4) , the theoretical viability calculated from these equations and the experimental viability obtained from stability tests were compared. As shown in [Fig. 5,](#page-5-0) there was no significant difference between the predicted and experimental viability during storage at $4 °C$ over 12 mth, confirming that the theoretical viability from Equation (3) can be used as a prediction model of stability of this strain in dried feed pellets. On the other hand, a great difference between the predicted experimental viability was found at 30 \degree C storage. The experimental viability followed the linear regression equation within

 $*$ Values with different superscripted lowercase letters (a-d) are significantly different using Duncan's multiple range test ($p < 0.05$).

Fig. 4. Arrhenius plot for the inactivation of *L. lactis* 1464 in the pellets dried at 70 °C.

4 mth and exhibited a higher cell reduction than viability from the prediction model. It was found that the experimental k value was approximately 1.4 times higher than the predicted k value. This was probably due to a change in the physical state of the dried pellets during accelerated storage testing ([Labuza and Riboh, 1982; Karmas](#page-6-0) [et al., 1992\)](#page-6-0). Another possible reason why the model overestimates is a possible contribution of nonenzymatic browning which is strongly temperature-dependent (Karmas et al., 1992; Kurtmann et al., 2009a, 2009b). The rate of browning is low below a critical temperature, above which the rate of the reaction increases substantially [\(Roos, 2001](#page-6-0)). Nonenzymatic browning is not always prevented in the glassy state. The reaction rates were much lower at temperatures below Tg compared with temperatures above Tg (Kawai et al., 2005). Few studies have been successful in predicting the viability of lactic acid bacteria during storage. Hamsupo et al. (2005) reported that there was no significant difference in viability between prediction and experimental survival rates of spray-dried Lactobacillus reuteri KUB-AC5 at 4 °C and 30 °C for 4 mth. This could indicate that the predicted model may vary according to the strain of microorganisms and also the capability of the protective agents used [\(Lapsiri et al., 2012\)](#page-6-0).

In conclusion, this study indicated that it is possible to prepare shrimp feed pellet with high viable cell numbers of probiotic bacteria using fluidized bed drying. The viability of the strain during drying varied depending on the drying temperature, culture pH and

Fig. 5. Comparison of estimated and experimentally measured viability of L. lactis 1464 during storage at 4 \degree C and 30 \degree C.

type of protectants. However, the remaining viable cells in pellets were $10^6 - 10^8$ CFU/g with a moisture content below 11% after drying at every drying temperature which met the level requirements for probiotic products. The study of probiotic product storage revealed that the drying and storage temperatures are critical factors for microbial survival. The addition of some protective agents enhanced viability during drying and storage. Moreover, the accelerated storage testing was a rapid and simple technique for estimating the long-term shelf life of this probiotic product but at a low specific temperature of 4° C only in the model.
