Abstract  The purpose of the present paper was to investigate the flow and heat transfer of Jeffery fluid past a linearly stretching sheet with the effect of a magnetic dipole. The governing differential equations of motion and heat transfer are transformed into nonlinear coupled ordinary differential equations (ODEs) using appropriate similarity transformations. Then the ODEs are solved by adopting two different schemes, Runge–Kutta with shooting technique and series solution based on GA and NM. The effect of various physical parameters including ferromagnetic interaction parameter ($\beta$), Deborah number ($\gamma_1$), Prandtl number ($Pr$), suction/injection parameter ($S$), ratio of relaxation to retardation times ($\lambda_2$) on velocity and temperature profiles is illustrated graphically and in tabular form by considering two types of thermal process namely prescribed surface temperature (PST) and prescribed heat flux (PHF). Comparison with available results for particular cases is found an excellent agreement.

1. Introduction

Boundary layer flow and heat and mass transfer over a stretching surface have received spectacular attention due to their extensive applications in industry, engineering, and metallurgy process such as production of polythene and paper, polymer extrusion, cooling of elastic sheets, wire drawing, fiber technology, continuous stretching of plastic films, hot rolling, crystal growing and cooling of an infinite metallic plate in a cooling bath. Heat transfer is important because the rate of cooling can be controlled and final products of desired characteristics might be achieved. Flow over a flat plate with uniform free stream has been examined by Blasius [1]. The boundary layer flow over a continuous moving flat surface was initially investigated by Sakiadis [2]. Crane [3] established a simple closed form analytical solution for two-dimensional incompressible boundary layer flow over a linear stretching sheet with the velocity proportional to the distance from the origin. This problem was extended to heat and mass transfer with the effect of suction or blowing by Gupta and Gupta [4]. Ariel [5] considered the problem of boundary layer flow of a viscous fluid by a stretching sheet using homotopy perturbation method. Some of the collections of research papers existing in the open literature can be found in [6–11].

CrossMark
However, all the above-mentioned researches are restricted to Newtonian fluid flows. Fluids that do not obey the Newton’s law of motion are called non-Newtonian fluids. Study of non-Newtonian fluids has received great attention in modern technologies such as geothermal engineering, geophysical, astrophysical bio-fluid and petroleum industries, and some of the examples of non-Newtonian fluids are toothpaste, waste fluids, and food products. Many constituent relations of non-Newtonian fluids has received great attention in modern technologies such as geothermal engineering, geophysical, astrophysical bio-fluid and petroleum industries, and some of the examples of non-Newtonian fluids are toothpaste, waste fluids, and food products. Many constituent relations of non-Newtonian fluids have been considered in the literature due to its versatile nature. Here we considered Jeffrey fluid model for non-Newtonian fluids. Sahoo [12] performed heat transfer analysis of non-Newtonian fluid over a stretching surface. He applied finite difference method with shooting technique to obtain simultaneous effects of the partial slip and the third-grade fluid parameter on velocity and temperature fields.

Sandeep et al. [13] investigated the stagnation point flow of MHD Jeffrey nanofluid over a stretching surface with induced magnetic field and chemical reaction. Raju et al. [14] analyzed the effects of nonlinear thermal radiation on 3D Jeffrey fluid flow over a stretching/shrinking surface in the presence of homogeneous-heterogeneous reactions, non-uniform heat source/sink, and suction/injection. Rashidi et al. [15] performed mixed convective laminar, incompressible flow and heat analysis transfer of viscoelastic fluid over a permeable wedge with thermal radiation by employing homotopy analysis method (HAM).

Hayat et al. [16] considered Jeffery fluid flow in a porous channel in the presence of a transverse magnetic field. They found a semi-analytical solution to the highly nonlinear problem by applying HAM. Hayat et al. [17] determined three-dimensional boundary layer flow of Jeffrey fluid past a stretching surface by employing HAM. Animasaun et al. [18] studied the motion of viscoelastic fluid toward a stretching sheet in the presence of induced magnetic field for the case of unequal diffusivities of homogeneous–heterogeneous reaction with thermal radiation. Nadeem et al. [19] investigated the effect of nanoparticles on two-dimensional steady flow of a Jeffrey fluid past a stretching surface. Rashidi and Erfani [20] analyzed thermal-diffusion and soret effect on steady MHD convective slip flow due to a rotating disk with viscous dissipation and Ohmic heating using the DTM-Pade technique.

Malik et al. [21] presented the Jeffrey fluid flow with a pressure-dependent viscosity. They considered two types of flow problem, Couette and Poiseuille flow for the Jeffrey fluid. Raju et al. [22] have discussed MHD chemically reacting boundary layer flow of Jeffrey nanofluid over a permeable cone in a porous medium with the effect of thermophoresis, Brownian motion, and thermal radiation. Sandeep et al. [23] studied heat and mass transfer of convective non-Newtonian nanofluids over a permeable stretching sheet with the effects of transverse magnetic field and suction/injection. Abolbashari et al. [24] examined entropy analysis for MHD nano-fluid past a permeable stretching surface. They considered four different types of nanoparticles with water as the base fluid. Nurayana et al. [25] studied the flow of micropolar ferromagnetic fluid due to stretching of an elastic sheet in the presence of an applied magnetic field.

In view of all the above-stated application, the main objective of the present article was to explore the flow and heat transfer behavior of Jeffery fluid over a stretching surface with the influence of magnetic dipole. Effect of non-dimensional governing parameters such as ferromagnetic interaction parameter, suction/injection parameter, Deborah number, the ratio of relaxation to retardation times, Prandtl number on velocity and temperature fields is analyzed through the graph.

2. Mathematical formulation

2.1. Magnetic dipole

Magnetic liquid flow is influenced by the dipole field whose permanent magnetic scalar potential is taken as

$$\Phi = \frac{\gamma}{2\pi} \left( \frac{x}{x^2 + (y + a)^2} \right).$$

2.2. Local physical parameters

However, all the above-mentioned researches are restricted to Newtonian fluid flows. Fluids that do not obey the Newton’s law of motion are called non-Newtonian fluids. Study of non-Newtonian fluids has received great attention in modern technologies such as geothermal engineering, geophysical, astrophysical bio-fluid and petroleum industries, and some of the examples of non-Newtonian fluids are toothpaste, waste fluids, and food products. Effect of non-dimensional governing parameters such as ferromagnetic interaction parameter, suction/injection parameter, Deborah number, the ratio of relaxation to retardation times, Prandtl number on velocity and temperature fields is analyzed through the graph.

2. Mathematical formulation

2.1. Magnetic dipole

Magnetic liquid flow is influenced by the dipole field whose permanent magnetic scalar potential is taken as

$$\Phi = \frac{\gamma}{2\pi} \left( \frac{x}{x^2 + (y + a)^2} \right).$$

2.2. Local physical parameters
where $\gamma$ is the strength of magnetic field. The components of magnetic field intensity $H_x$ and $H_y$ along the coordinates $x$ and $y$ axes are

$$H_x = -\frac{\partial \Phi}{\partial x} = \frac{\gamma}{2\pi} \left( \frac{x^2 - (y + a)^2}{(x^2 + (y + a)^2)^{3/2}} \right),$$

(2)

$$H_y = -\frac{\partial \Phi}{\partial y} = \frac{\gamma}{2\pi} \left( \frac{2x(y + a)}{(x^2 + (y + a)^2)^{3/2}} \right),$$

(3)

The resultant magnitude $H$ of the magnetic field intensity is given by

$$H = \left[ \left( \frac{\partial \Phi}{\partial x} \right)^2 + \left( \frac{\partial \Phi}{\partial y} \right)^2 \right]^{1/2},$$

(4)

$$\frac{\partial H}{\partial x} = -\frac{\gamma}{2\pi} \left( \frac{2x}{(y + a)^2} \right),$$

(5)

$$\frac{\partial H}{\partial y} = \frac{\gamma}{2\pi} \left( \frac{-2x}{(y + a)^3} + \frac{4x^2}{(y + a)^3} \right),$$

(6)

The variation of magnetization $M$ can be considered as a linear function of temperature [26].

$$M = K'(T_c - T),$$

(7)

where $K'$ is a pyromagnetic coefficient and $T_c$ is the Curie temperature. However, the following point is essential for the occurrence of ferrohydrodynamic interaction: (i) the fluid is at a temperature $T$ different from $T_c$ and (ii) the external magnetic field is inhomogeneous. Once the ferromagnetic fluid approaches Curie temperature, there is no further magnetization. Characteristic for physical significance is very important, as Curie temperature is very high, that is 1043 K for iron.

### 2.2. Flow analysis

Let us consider a two-dimensional viscous incompressible flow of Jeffrey fluid, electrically non-conducting past a stretching surface under the impact of the magnetic field induced by the magnetic dipole. A stretching sheet is considered along the $x$-axis with velocity $u_x = cx$ and $y$-axis is normal to it as shown schematically in Fig. 1. A magnetic dipole is situated in the center of $y$-axis and distance “$a$” from the sheet. Due to a dipole, magnetic field points in the positive $x$-direction and rises the magnetic field strength to marinate the ferrofluid.

It is also supposed that the uniform temperature at the surface and Curie temperature $T_c$, while the temperature of the ambient ferrofluid far from the surface of the sheet is $T_w = T_c$, and unable to magnetize until they start to cool after coming into the thermal boundary layer area near to the sheet.

The necessary equations for Jeffrey model can be written as

$$\tau = \rho I + \kappa$$

(8)

$$\kappa = \frac{\mu}{1 + \lambda_2} \left[ R_1 + \lambda_1 \left( \frac{\partial R_1}{\partial T} + V \cdot \nabla \right) R_1 \right]$$

(9)

where $\tau$ is the Cauchy stress tensor, $\kappa$ is extra stress tensor, $\mu$ is the dynamic viscosity, $\lambda_2$ and $\lambda_1$ are material parameters of Jeffrey fluid and $R_1$ is the Rivlin-Ericksen tensor defined by

$$R_1 = (\nabla V) + (\nabla V)^T.$$  

(10)

Using the boundary layer approximation, the continuity and momentum equations of Jeffrey fluid are listed below:

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0,$$

(11)

$$u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \frac{\mu}{\rho} M^2 \frac{\partial H}{\partial x} + \frac{v}{1 + \lambda_2} \left[ \frac{\partial^2 u}{\partial y^2} + \lambda_1 \left( u \frac{\partial^2 u}{\partial x \partial y} + \frac{\partial^3 u}{\partial x \partial y^2} \right. \right.$$

$$- \frac{\partial u}{\partial x} \frac{\partial^2 u}{\partial x \partial y} + \frac{\partial^2 u}{\partial y \partial x})],$$

where $(u, v)$ are the velocity components along the $(x, y)$ directions, respectively. $\lambda_1$ is the relaxation time, $\lambda_2$ is the ratio of relaxation to the retardation times, $\rho$ is the density of the fluid, $\mu$ is the dynamic viscosity, $v = \xi$ is the kinematic viscosity, $\mu_0$ is the magnetic permeability, $k$ is the thermal conductivity, $c_p$ is specific heat, $M$ is the magnetization, and $H$ is the magnetic field.

The relevant boundary conditions on velocity profile are

$$u = u_w = cx, \quad v = v_u, \quad \text{at} \quad y = 0$$

(13)

$$u \to 0, \quad \frac{\partial u}{\partial y} \to 0, \quad \text{as} \quad y \to \infty$$

where $c > 0$ is stretching rate of sheet, and $v_u$ is the suction/injection velocity.

To solve the governing Eq. (12), following similarity transformations are used [26]

$$\Psi(\xi, \eta) = \frac{\mu}{\rho} \xi \cdot f(\eta), \quad \xi = \sqrt{\frac{\mu}{\rho}} x, \quad \eta = \sqrt{\frac{\mu}{\rho}} y$$

(14)

$$\Psi(\xi, \eta)$$ is the stream function and $\xi, \eta$ are the dimensionless coordinates

(15)

The velocity components can be defined as

$$u = \frac{\partial \Psi}{\partial y} = c x \cdot f'(\eta), \quad v = -\frac{\partial \Psi}{\partial x} = -\sqrt{cv} \cdot f(\eta)$$

(16)

Substituting Eq. (16) in Eq. (12), and comparing the coefficients of like powers up to order $\xi^2$, we get the fourth-order nonlinear ordinary differential equations:

![Figure 1](Image 67x92 to 263x236)
\[ f'' - (1 + \lambda_2)(f'^2 - ff'') + \gamma_1(f'f'' - f'^2) - (1 + \lambda_2) \frac{2\theta_1}{(\eta + \varepsilon_1)^2} = 0, \]  
(17)

In view of the transformations, Eq. (13) takes the following non-dimensional form
\[ f = S, \quad f' = 1 \text{ at } \eta = 0 \]  
(18)

\[ f' \rightarrow 0, \quad f'' \rightarrow 0 \text{ as } \eta \rightarrow \infty \]

Here \( \gamma_1 = \lambda_1 c \) is the Deborah number and \( \beta = \frac{4\mu_0 k_B(T_c - T_w)}{\rho} \) is the ferromagnetic interaction parameter. \( S = \frac{v^2}{c_0^2} \) is the suction/injection parameter with \( S > 0 \) for suction and \( S < 0 \) for injection.

2.3. Heat transfer

The energy equation with the existence of magnetic fluid and viscous dissipation is given by [28]
\[ \rho c_p \left( \frac{\partial T}{\partial x} + \nu \frac{\partial T}{\partial y} \right) + \rho u \frac{\partial M}{\partial T} \left( \frac{\partial H}{\partial x} + \nu \frac{\partial H}{\partial y} \right) \]
\[ = k \frac{\partial^2 T}{\partial y^2} + \mu_0 \left( \frac{\partial u}{\partial y} \right)^2 + 2 \mu \left( \frac{\partial v}{\partial y} \right)^2 \]  
(19)

where \( \rho \) is the density of the fluid, \( c_p \) is specific heat, \( \mu_0 \) is the magnetic permeability, \( k \) is the thermal conductivity and \( T \) is the fluid temperature.

To solve the thermal boundary layer Eq. (8), we consider non-isothermal temperature boundary condition as
\[ T = T_w = T_c - A(\xi^2) \]  
(20)

\[ T \rightarrow T_c, \text{ as } \eta \rightarrow \infty \]

where \( A \) and \( D \) are positive constants and \( l = \sqrt{\nu/c} \) is the characteristic length.

Now we introduce the dimensionless variable \( \theta(\xi, \eta) \)
\[ \theta(\xi, \eta) \equiv \frac{T_c - T}{T_c - T_w} = \theta_1(\eta) + \xi^2 \theta_2(\eta), \]  
(21)

where \( T_c - T_w = A(\xi^2) \) for PST, \( T_c - T_w = \frac{Q}{\rho} (\xi^2)^{\frac{3}{2}} \) for PHF.

Substituting Eq. (21) in Eq. (19) we obtain non-dimensional thermal boundary layer equations up to order \( \xi^2 \)
\[ \theta'_1 + Pr(\theta'_1 - 2f'\theta) + \frac{2\theta_1}{(\eta + \varepsilon_1)^2} = 0, \]  
(22)

\[ \theta'_2 - Pr(4f'\theta_2 - \theta_1) + \frac{2f_\theta^2}{(\eta + \varepsilon_1)^3} \]
\[ - \lambda \beta(\theta_1 - e) \left[ \frac{2f'}{(\eta + \varepsilon_1)^3} - \frac{4f}{(\eta + \varepsilon_1)^4} \right] = 0, \]  
(23)

where \( Pr = \frac{\nu}{\kappa} \) is Prandtl number, \( \lambda = \frac{c_p^2}{\rho k} \) is the viscous dissipation parameter, \( \varepsilon_1 = \frac{\sqrt{x_1^2}}{T_c - T_w} \) is the dimensionless distance from the origin to the magnetic dipole and \( e = \frac{T_c}{T_c - T_w} \) is the dimensionless Curie temperature ratio.

The boundary conditions (20) become
\[ \theta_1 = 1, \quad \theta_2 = 0, \text{ for PST} \]
\[ \theta'_1 = 1, \quad \theta'_2 = 0, \text{ for PHF} \]  
(24)

\[ \theta_1 \rightarrow 0, \quad \theta_2 \rightarrow 0, \text{ as } \eta \rightarrow \infty \]

The quantities of physical interest are the local skin-friction coefficient and the local Nusselt number can be expressed as
\[ C_f \equiv \frac{-2\tau_v}{\rho(\nu)^2}, \quad Nu \equiv \frac{q_w}{-k(T_c - T_w)} \]  
(25)

where \( \tau_v \) is the surface shear stress and \( q_w \) is the surface heat flux are
\[ \tau_v = \mu \left( \frac{\partial u}{\partial y} \right) |_{y=0}, \quad q_w = -\left( \frac{\partial T}{\partial y} \right) |_{y=0} \]  
(26)

Using Eqs. (16) and (21) we have
\[ C_f \equiv \frac{2T''(0)}{\nu}, \quad Nu \equiv \frac{(\theta'_1(0) + \xi^2 \theta_2(0))}{(\theta_1(\infty) + \theta_2(\infty))} \]  
(27)

where \( Re_s = \frac{2\nu^2}{\nu} \) is the local Reynolds number. It is superficial that the flow is influenced by the ferromagnetic parameter \( \beta \). It is more fascinating and suitable to exchange the dimensionless wall heat transfer rate \(-\theta'' = -[\theta'_1(0) + \xi^2 \theta_2(0)] \) by the independent of the distance \( \xi \), a ratio \( \theta''(0) = \frac{\theta'_1(0)}{\theta_1(\infty)} \) called the coefficient of the heat transfer rate at the sheet.

3. Numerical solution

Transformed differential Eqs. (17), (22) and (23) with relevant boundary conditions (18) and (24) are highly nonlinear and possess no analytically solution and must be solved numerically by efficient Runge-Kutta method based on shooting technique with the help of software package Matlab. The higher order differential equations are converted into the set of eight first-order simultaneous equations and they require eight initial conditions as a function of multivariate of initial condition values. This method works by considering the boundary conditions as a function of initial condition at some points, converting the boundary value problem to get the initial conditions. The boundary values calculated have to be matched with the real boundary values. An essential part of this method is to select the suitable finite value for \( \eta_\infty \). The maximum value of \( \eta_\infty \) is taken equal to 15 in order to achieve the far field boundary condition asymptotically.

4. Series solution based on genetic algorithm and Nelder-Mead method

4.1. Series solution

Our interest now is to find the series solutions of velocity \( f(\eta) \) and temperature \( \theta_1(\eta) \). For these solutions we write
Heat transfer analysis of Jeffery fluid flow

\[ f(\eta) = f_0(\eta) + \sum_{m=1}^{\infty} \frac{1}{m!} \frac{\partial^m f(\eta, p)}{\partial \eta^m} \bigg|_{\eta = 0} p^m \]  \hspace{1cm} (28)

\[ \theta(\eta) = \theta_{10}(\eta) + \sum_{m=1}^{\infty} \frac{1}{m!} \frac{\partial^m \theta(\eta, p)}{\partial \eta^m} \bigg|_{\eta = 0} p^m \]  \hspace{1cm} (29)

Initial guesses \( f_0 \) and \( \theta_{10} \) of \( f(\eta) \) and \( \theta(\eta) \) are chosen as

\[ f_0(\eta) = S + 1 - \exp(-\eta), \quad \theta_{10}(\eta) = \exp(-\eta) \]  \hspace{1cm} (30)

The auxiliary linear operators are selected in the following forms:

\[ L_f = \frac{d^2 f}{d\eta^2} - \frac{df}{d\eta} \bigg|_{\eta = 0} \]  \hspace{1cm} (31)

\[ L_{\theta_i} = \frac{d^2 \theta_i}{d\eta^2} - \theta_i \]  \hspace{1cm} (32)

The zeroth order deformation problems are constructed as

\[ (1 - q) L_f[\hat{f}(\eta, p) - f_0(\eta)] = q \theta_2 N_f[\hat{f}(\eta, p) - \hat{\theta}_1(\eta, p)] \]  \hspace{1cm} (33)

\[ (1 - q) L_{\theta_i}[\hat{\theta}_i(\eta, p) - \theta_{10}(\eta)] = q \theta_3 N_{\theta_i}[\hat{\theta}_i(\eta, p) - \hat{\theta}_1(\eta, p)] \]  \hspace{1cm} (34)

\[ \hat{f}(\eta, p) = S_{l=0}, \quad \frac{\partial \hat{f}(\eta, p)}{\partial \eta} \bigg|_{\eta = 0} = 1, \]  \hspace{1cm} (35)

in which the nonlinear operators \( N_f \) and \( N_{\theta_i} \) are

\[ N_f[\hat{f}(\eta, p) - \hat{\theta}_1(\eta, q)] = \frac{\partial^2 \hat{f}(\eta, p)}{\partial \eta^2} - (1 - \lambda_2) \left( \frac{\partial \hat{f}(\eta, p)}{\partial \eta} \right)^2 - \hat{f}(\eta, p) \frac{\partial^2 \hat{f}(\eta, p)}{\partial \eta^2} \]  \hspace{1cm} (36)

\[ N_{\theta_i}[\hat{\theta}_i(\eta, p) - \hat{\theta}_1(\eta, q)] = \frac{\partial^2 \hat{\theta}_i(\eta, p)}{\partial \eta^2} + \left( \frac{\partial \hat{f}(\eta, p)}{\partial \eta} \right)^2 - \hat{\theta}_i(\eta, q) \frac{\partial^2 \hat{f}(\eta, p)}{\partial \eta^2} - (1 - \lambda_2) \frac{2 \beta \hat{\theta}_i(\eta, q)}{(\eta + s_i)^2}, \]  \hspace{1cm} (37)

when \( p = 0 \) and \( p = 1 \), we have

\[ \hat{f}(\eta; 0) = f_0(\eta), \quad \hat{f}(\eta; 1) = f(\eta). \]  \hspace{1cm} (38)

\[ \hat{\theta}_1(\eta; 0) = \theta_{10}(\eta), \quad \hat{\theta}_1(\eta; 1) = \theta(\eta). \]  \hspace{1cm} (39)

By Taylor theorem, we obtain

\[ f_\infty(\eta) = \frac{1}{m!} \frac{\partial^m f(\eta, p)}{\partial \eta^m} \bigg|_{\eta = 0} p^m \]  \hspace{1cm} (40)

\[ \theta_{\infty}(\eta) = \frac{1}{m!} \frac{\partial^m \theta(\eta, p)}{\partial \eta^m} \bigg|_{\eta = 0} p^m \]  \hspace{1cm} (41)

The auxiliary parameters are so properly chosen that the series (40) and (41) converge at \( p = 1 \), so we have

\[ \hat{f}(\eta, p) = f_0(\eta) + \sum_{m=1}^{\infty} f_\infty(\eta)p^m, \]  \hspace{1cm} (42)

\[ \hat{\theta}_i(\eta, p) = \theta_{10}(\eta) + \sum_{m=1}^{\infty} \theta_{\infty}(\eta)p^m \]  \hspace{1cm} (43)

4.2. Genetic algorithm and Nelder Mead method

Genetic algorithm (GA) is an optimization tool based on Darwinian evolution which has been developed in 1976, but its utilization in heat transfer problems has not been tested. In fact GA plays an important role when multiple parameters are involved. The main procedure is inspired by the Darwinian theory of evolution “The survival of the fittest.” The genetic algorithm is a random search technique. Major advantage of GA is that the demand about computer memory for nonlinear problems is minimum. Genetic algorithm will be helpful for future even to get minimum and maximum solutions to satisfy
inequality relationships as well [30,31]. There are five main decision points in the procedure given below:

There are several techniques for optimization such as analytical approach, downhill simplex method, gradient descent, and Newton’s method. Moreover, the Nelder-Mead method is direct search simplex algorithm published in 1965 and is one of the most widely used methods for nonlinear unconstrained optimization. The Nelder-Mead method minimizes a nonlinear function of n real variables without taking any derivative. The function is evaluated at each point of the simplex structure formed by (n + 1) points and the vertex with the highest value is replaced by a new point with a lower value. It continues until the minimum value of the function is achieved [32].

## 5. Result and discussion

The purpose of the present article was to investigate the boundary layer flow and heat transfer of Jeffery fluid flow over a stretching surface with the effect of the magnetic dipole and suction/injection. Influence of various pertinent parameters is discussed with the help of figures and tables. The default values of the parameters for current work are considered as $Pr = 0.72$, $\beta = 0.2$, $\gamma_1 = 0.2$, $\gamma = 0.1$, $S = 0.1$, and $\xi_1 = 1.0$. To check the efficiency of the numerical procedure, the present computational results for $-\theta'_1(0)$ are carried out for different values of $Pr$ and compared with those reported by Chen [7] and Abel et al. [29] in Table 1 and found an excellent agreement. The numerical values of skin friction coefficient $-f''(0)$, Nusselt number $-\theta'_1(0)$ in PST and surface temperature $1/\theta_1(0)$ in PHF case are given for numerical solution and series solution based on GA and NM case for various values of the physical parameter presented in Table 2. This table is evident that Nusselt number for PST is directly proportional to Prandtl number, Deborah number, and suction/injection parameter, and inversely proportional to ferromagnetic interaction parameter, the ratio of relaxation and retardation times. Similarly, surface temperature for PHF case and skin friction coefficient is directly proportional to ferromagnetic interaction parameter, the ratio of relaxation and retardation times, and inversely proportional to Prandtl number, Deborah number. Table 3 identifies the fast convergence of optimal series solution. It has been observed that good convergence is obtained at even third iteration and excellent solution can be taken in only 5.463 sec.

### Table 1: Comparison of Nusselt number $-\theta'_1(0)$ for the case $\beta = \lambda = \lambda_2 = \gamma_1 = S = 0$.

Series solution based on GA and NM
The influence of applied external magnetic field due to magnetic dipole is demonstrated through ferromagnetic interaction parameter $b$. The existence of magnetic field acts as the delaying force on the velocity profile and then as $b$ increases so does the delaying force and hence results in flattening the axial velocity $f_0(\eta)$. This is because of the fact that variation of magnetic parameter leads to deviation of Lorentz force and this force produces a more resistance to the transport phenomena. Also noticed that in the presence of magnetic field, the velocity profile is less as compared with the hydrodynamic case ($b = 0$) for both PST and PHF cases as seen in Fig. 2(a) and (b). Because there is an intervention between the fluid motion and the action of the applied magnetic field, this kind of intervention reduces the velocity and increasing frictional heating involving within the fluid layers which are answerable for the enhancement in the thermal transport as cleared in Fig. 3(a) and (b) for case PST and PHF.

Fig. 4(a) and (b) displays the influence of Deborah number ($\gamma_1$) on temperature profile for two types PST and PHF respectively.

The influence of applied external magnetic field due to magnetic dipole is demonstrated through ferromagnetic interaction parameter $b$. The existence of magnetic field acts as the delaying force on the velocity profile and then as $b$ increases so does the delaying force and hence results in flattening the axial velocity $f_0(\eta)$. This is because of the fact that variation of magnetic parameter leads to deviation of Lorentz force and this force produces a more resistance to the transport phenomena. Also noticed that in the presence of magnetic field, the velocity profile is less as compared with the hydrodynamic case ($b = 0$) for both PST and PHF cases as seen in Fig. 2(a) and (b). Because there is an intervention between the fluid motion and the action of the applied magnetic field, this kind of intervention reduces the velocity and increasing frictional heating involving within the fluid layers which are answerable for the enhancement in the thermal transport as cleared in Fig. 3(a) and (b) for case PST and PHF.

Fig. 4(a) and (b) displays the influence of Deborah number ($\gamma_1$) on temperature profile for two types PST and PHF respectively.
Figure 4  Effect of Deborah parameter $\gamma_1$ on velocity: (a) for PST and (b) for PHF.

Figure 5  Effect of ratio of relaxation and retardation time $\lambda_2$ on temperature: (a) for PST and (b) for PHF.

Figure 6  Effect of suction/injection $S$ on temperature: (a) for PST and (b) for PHF.
A decrease in temperature profile $\theta_1$ for both types PST and PHF. Physically $c_1$ is proportional to retardation time $k_1$; hence, a large retardation time of any material makes it less viscous, which may result in an increase in its motion, which consequently weakens the thermal boundary layer thickness and lower temperature profile.

Fig. 5(a) and (b) portrays the effect of the ratio of relaxation to retardation time parameter $k_2$ on temperature profile $h$. From figures, it observed that temperature profile is gradually increasing with an increase in the value of $k_2$ for both cases PST and PHF. An increase in $k_2$ implies to an increase in relaxation time and decrease in retardation time. This change in relaxation and retardation times elucidates the rise in temperature and thicker thermal boundary layer thickness.

Fig. 6(a) and (b) represents the influence of suction/injection parameter ($S$) on temperature profile for both cases PST and PHF. It is evident temperature profile depreciates with increasing suction parameter ($S > 0$) whereas for injection ($S < 0$) opposite behavior is noted. Here negative values signify the injection and positive values signify the suction. Moreover, the thermal boundary layer thickness reduces with the increase in $S$ for both PST and PHF cases.

Fig. 7(a) and (b) draws to analyze the effect of Prandtl number on temperature profile $\theta_1$. It is seen that temperature decreases with respect to $Pr$ for both PST and PHF cases. This is due to the fact that fluid has relatively lower thermal conductivity for a large value of Prandtl number, which reduces the conduction and thermal boundary layer thickness, as a result temperature decreases.

Fig. 8(a) and (b) highlights the skin friction coefficient and Nusselt number with the variation of ferromagnetic interaction parameter $\beta$ for different values of Prandtl number $Pr$. It is evident that skin friction coefficient increases by an increase in $\beta$ whereas depreciates for $Pr$. Also by increasing the value of Prandtl number $Pr$ there is an increase in Nusselt number, as the fluid with large Prandtl number $Pr$ has higher heat capacity and hence increases the heat transfer rate seen in Fig. 8(b).

Fig. 9(a) and (b) illustrates the effect of suction parameter $S$ on skin friction coefficient and Nusselt number with the variation of $\beta$. From Fig. 9(a) it can be observed that the graph
of skin friction coefficient increases for $\beta > 2$ and decreases for $\beta < 2$. Also for $S > 0$ the rate of heat transfer is enhanced, whereas the reverse trend is occurred for $\beta$ as shown in Fig. 9(b).

6. Concluding remarks

Fourth-fifth order Runge-Kutta numerical method with shooting technique and series solution based on GA and NM is employed on incompressible boundary layer flow and heat transfer of a Jeffrey fluid past a linearly stretching sheet with the effect of magnetic dipole for two types of heating process, namely prescribed surface temperature (PST) and prescribed heat flux (PHF). The results of several physical parameters such as ferromagnetic interaction parameter ($\beta$), Deborah number ($\gamma_2$), ratio of relaxation to retardation times ($\gamma_1$), suction/injection parameter ($S$), Prandtl number ($Pr$) on velocity and temperature profiles are examined and discussed graphically in details. Finally, some important observations based on the present study are as follows:

- Ferromagnetic interaction parameter $\beta$ decreases velocity and increases temperature.
- The effect of Prandtl number $Pr$ is to decrease the temperature for both PST and PHF cases.
- The influence of suction/injection parameter is to decrease the thermal boundary layer thickness.
- Skin friction coefficient is an increasing function of $\beta$, $\gamma_2$, $S$ and decreasing function of $\gamma_1$, $Pr$.
- Local Nusselt number has increasing effect with increase in Deborah number, suction/injection parameter and Prandtl number, while opposite nature is seen for surface temperature.
