ABSTRACT: Direct searches for WIMPs are sensitive to physics well below the weak scale. In the absence of light mediators, it is fruitful to apply an Effective Field Theory (EFT) approach accounting only for dark matter (DM) interactions with Standard Model (SM) fields. We consider a singlet fermion WIMP and effective operators up to dimension 6 which are generated at the mass scale of particles mediating DM interactions with the SM. We perform a one-loop Renormalization Group Evolution (RGE) analysis, evolving these effective operators from the mediators mass scale to the nuclear scales probed by direct searches. We apply our results to models with DM velocity-suppressed interactions, DM couplings only to heavy quarks, leptophilic DM and Higgs portal, which without our analysis would not get constrained from direct detection bounds. Remarkably, a large parameter space region for these models is found to be excluded as a consequence of spin-independent couplings induced by SM loops. In addition to these examples, we stress that more general renormalizable models for singlet fermion WIMP can be matched onto our EFT framework, and the subsequent model-independent RGE can be used to compute direct detection rates. Our results allow us to properly connect the different energy scales involved in constraining WIMP models, and to combine information from direct detection with other complementary searches, such as collider and indirect detection.

1 Introduction

The nature of dark matter (DM) is one of the main open questions in particle physics. Among many candidates [1–3], a Weakly Interacting Massive Particle (WIMP) with relic abundance obtained through thermal freeze-out [4–7] is quite appealing. Motivated frameworks for physics beyond the Standard Model (SM) naturally have a WIMP candidate [8–13], and it is suggestive that the same theory addressing the hierarchy problem also provides us with a DM candidate. Another exciting feature of the WIMPs is the fact that their

typical couplings to SM particles are in the correct ballpark to give signals at colliders, direct and indirect detection experiments. Each of these searches is more sensitive to a certain parameter space region, so the WIMP paradigm can be tested with multiple and complementary methods.

Direct detection experiments play a peculiar role among these searches, since they probe energy scales much lower than the weak scale. For example, a 1 TeV DM particle with a typical velocity $v/c \sim 10^{-3}$ scattering off a Xenon target cannot lead to a nuclear recoil energy larger than about 200 keV. The relevant physics at such small scales can be described by a non-relativistic Effective Field Theory (EFT), by integrating out short-distance effects and keeping only the relevant low-energy degrees of freedom [14–22]. The analysis of other searches requires to go beyond this non-relativistic EFT. A simplifying hypothesis is to assume that the DM is the *only* non-SM particle experimentally accessible [23–35], with interactions parameterized by non-renormalizable operators originated from the exchange of heavy mediator particles. The validity of this approach does not extend all the way up to the LHC center of mass energy [36–42], motivating the recent effort towards simplified models with mediator fields in the spectrum [43–59].

In this work we develop a formalism to connect DM models to nuclear scales probed by direct detection. As shown in refs. [60–69], there are examples where this large separation of scales has remarkable implications when a comparison with experiments is attempted. We focus on models for fermion DM with no SM gauge charge, and we assume that all the non-SM particles (with the possible exception of the DM itself) are above the weak scale. Fermion singlets cannot communicate with the SM at a renormalizable level, thus DM interactions must be necessarily mediated by these heavy particles. Once they are integrated out, it is possible to make a connection with nuclear scales that does not depend on the specific model we started from. This general analysis is the goal of our paper, where we connect physics at the mediator mass scales with direct detection observables. A generic model of singlet fermion DM, Dirac or Majorana, can be matched onto our EFT framework at the mass scale of the mediator particles.

Our setup is sketched in figure 1. At high energy scales we imagine the DM field χ embedded in an ultraviolet (UV) complete model. In our model-independent analysis we can neglect the UV details and consider the low-energy EFT with only χ and the SM fields in the spectrum. As emphasized in ref. [68], a systematic study allows us to identify mixing among operators and bound interactions that are poorly constrained otherwise. For this reason we start from the most general basis of operators up to dimension 6, defined at the EFT cutoff Λ , which corresponds to the mediators mass scale. The operators are evolved via a proper one-loop Renormalization Group (RG) analysis down to the ElectroWeak Symmetry Breaking (EWSB) scale, where the W and Z gauge bosons, the Higgs boson and the top quark are integrated out. This procedure defines a different EFT, with only strong and electromagnetic gauge interactions and 5 quark flavors. We perform the one-loop RG analysis in this EFT as well, taking into account threshold corrections to the Wilson coefficients from integrating out the b and c quarks and the τ lepton, and evolving down to the nuclear scale $\mu \sim 1\text{--}2\text{ GeV}$ at which hadronic matrix elements are evaluated (see e.g. [22, 70, 71]).

Figure 1. Effective Field Theories used in this work. The fields mediating DM interactions with the SM are integrated out at the scale Λ . The operators of the SM_χ EFT are evolved down to the EWSB scale, where electroweak states are integrated out. There a matching onto the $EMSM_\chi$ EFT is performed. Finally, the operators are evolved down to the nuclear scale probed by direct searches.

Why is this study relevant? After all, RG corrections are of the order of $\log(\Lambda/1 \text{ GeV})$ multiplied by a loop factor, and pushing Λ to 10 TeV barely changes the order of magnitude for the rate. One may question the usefulness of a precise evaluation of the cross section in a pre-discovery era. We are certainly not after such a precision, and our focus is rather on models where loop effects are the dominant contribution.

The only DM interactions at the nuclear scale relevant for direct detection involve the u, d, s quarks, gluons and photons. However, many motivated models have mediator fields coupling the DM particle to heavy SM states and/or leptons. In these cases the main contribution to direct detection rates comes from loop effects. Furthermore, different light quarks couplings yield direct detection cross sections which could differ by orders of magnitude, as Goodman and Witten showed in their seminal paper [72]. If the mediator fields induce suppressed couplings to light quarks (e.g. DM velocity-suppressed and/or spin-dependent interactions), loop-induced couplings to non-suppressed operators are again the dominant contribution. The best current experimental limits come from XENON100 [73] and LUX [74], and will be significantly improved soon by SCDMS, XENON1T, DARKSIDE G2 and LZ (see for example ref. [75]). They rule out electroweak processes with Z boson exchange by orders of magnitude, and are therefore powerful enough to put constraints even on loop-induced processes.

The paper is structured as follows. The bases of independent operators for both the EFTs in figure 1 as well as matching conditions at the EWSB scale are discussed in section 2. The RGE equations in both EFTs are presented in section 3, with details on loop calculations contained in appendix B. The reader only interested in our results, not in their derivation, can safely jump from section 2 to section 4, where we present the applications of our results to spin-independent searches. Consistently with the spirit of this work, we focus on examples where the DM has either suppressed couplings to light quarks or couplings only to heavy SM states. In these cases our loop effects are the main contribution to spin-independent direct detection rates. In appendix D we give a straightforward recipe that allows one to apply our results and constrain UV complete fermion WIMP models that give rise to dimension 6 effective operators. Section 5 contains our conclusions.

2 The effective theories for singlet fermion dark matter

Our conceptual starting point is a renormalizable model for a fermion DM field χ that is a SM gauge singlet. Interactions between χ and the SM degrees of freedom ψ_{SM} are due to the exchange of mediator fields Φ . The typical mass of the Φ 's is assumed to be greater than the Fermi scale, and at such scales the full SM gauge symmetry $\text{SU}(3)_c \times \text{SU}(2)_L \times \text{U}(1)_Y$ is unbroken. The Lagrangian of the UV complete model schematically reads

$$\mathcal{L}_{\text{UV}} = \mathcal{L}_{\text{SM}} + \bar{\chi}(i\not{\partial} - m_\chi)\chi + \mathcal{L}_{\text{med}}(\psi_{\text{SM}}, \chi, \Phi). \quad (2.1)$$

Integrating out the mediators at the scale Λ generates what we call SM_χ EFT, containing only χ and the whole SM field content as its degrees of freedom. Many explicit realizations for \mathcal{L}_{UV} exist in the literature, and they can all be matched onto the SM_χ EFT at the cutoff scale Λ . The regime of validity of this EFT extends all the way down to the EWSB scale, where the heavy EW states (W , Z , h and t -quark) have to be integrated out and the residual gauge symmetry is $\text{SU}(3)_c \times \text{U}(1)_{\text{em}}$. For this reason we employ a different EFT below the EWSB scale, with only a $\text{SU}(3)_c \times \text{U}(1)_{\text{em}}$ gauge symmetry and 5 quark flavors, which we call EMSM_χ EFT (where EMSM stands for SM with only electromagnetic interactions). In the remaining part of this section we give a basis of independent operators for both EFTs up to mass dimension 6, as well as a prescription for how to match SM_χ EFT onto EMSM_χ EFT at the EWSB scale.

2.1 SM_χ effective theory

Right below the mediator scale Λ all the SM degrees of freedom are in the spectrum, and the $\text{SU}(3)_c \times \text{SU}(2)_L \times \text{U}(1)_Y$ SM gauge group is unbroken. Integrating out the mediators Φ in eq. (2.1) generates an infinite tower of higher dimensional operators

$$\mathcal{L}_{\text{SM}_\chi} = \mathcal{L}_{\text{SM}} + \bar{\chi}(i\not{\partial} - m_\chi)\chi + \sum_{d>4} \sum_{\alpha} \frac{c_\alpha^{(d)}}{\Lambda^{d-4}} \mathcal{O}_\alpha^{(d)}. \quad (2.2)$$

Our conventions for the SM Lagrangian \mathcal{L}_{SM} are summarized in appendix A.1. In particular, since SM fermions are in a chiral representation of the gauge group, we use the matter fields

$$\mathcal{F}_{\text{SM}} = \{q_L^{(i)}, u_R^{(i)}, d_R^{(i)}, l_L^{(i)}, e_R^{(i)}, H\}. \quad (2.3)$$

The index i runs over the three different SM fermion generations, and the gauge quantum numbers are assigned as in table 1. The index α runs over all gauge invariant operators of a given dimension d , with the dimensionless Wilson coefficients $c_\alpha^{(d)}$ encoding unresolved dynamics. These coefficients are renormalization-scale dependent, and we will quantify this dependence in the next section.

Without the need of specifying the responsible symmetry, we make sure the DM field is stable by requiring that every operator contains at least two χ fields. As an example, if DM is stabilized by a Z_2 symmetry, only operators with an even number of χ fields are allowed. Furthermore, our focus is on DM elastic scattering off target nuclei, thus we only

	q_L^i	u_R^i	d_R^i	l_L^i	e_R^i	H
SU(3) _c	3	3	3	1	1	1
SU(2) _L	2	1	1	2	1	2
U(1) _Y	+1/6	+2/3	-1/3	-1/2	-1	+1/2

Table 1. SM matter fields and gauge charges in the unbroken phase. q_L^i and l_L^i are left-handed fermions, u_R^i , d_R^i and e_R^i are right-handed fermions. The index i runs over the three generations.

Symbol	Operator	Symbol	Operator
\mathcal{O}_S	$\bar{\chi}\chi H^\dagger H$	\mathcal{O}_{M_B}	$\bar{\chi}\sigma^{\mu\nu}\chi B_{\mu\nu}$
\mathcal{O}_P	$\bar{\chi}\gamma^5\chi H^\dagger H$	\mathcal{O}_{E_B}	$\bar{\chi}\sigma^{\mu\nu}\chi \epsilon_{\mu\nu\rho\sigma}B^{\rho\sigma}$

Table 2. Basis of dimension 5 operators for the SM_χ Effective Theory.

need to consider operators with two DM fields. In our study we adopt the following basis of DM bilinears $\mathcal{O}_{\alpha\chi}$ ¹

$$\mathcal{O}_{\alpha\chi} = \{ \bar{\chi}\chi, \bar{\chi}\gamma^5\chi, \bar{\chi}\gamma^\mu\chi, \bar{\chi}\gamma^\mu\gamma^5\chi, \bar{\chi}\sigma^{\mu\nu}\chi \}. \quad (2.4)$$

Upon applying Fierz identities if necessary, each higher dimensional operator $\mathcal{O}_\alpha^{(d)}$ appearing in eq. (2.2) with $d \leq 6$ and relevant to our analysis can be written as a product of a DM bilinear and SM fields

$$\mathcal{O}_\alpha^{(d)} = \mathcal{O}_{\alpha\chi}^{(3)} \times \mathcal{O}_{\alpha\text{SM}}^{(d-3)}. \quad (2.5)$$

The part involving only SM fields $\mathcal{O}_{\alpha\text{SM}}^{(d-3)}$ has mass dimension $d-3$, is a SM gauge singlet but not necessarily a Lorentz singlet. We derive a complete basis of operators for the SM_χ EFT up to dimension 6 following this strategy: we first identify all possible gauge singlets $\mathcal{O}_{\alpha\text{SM}}^{(d-3)}$ by employing the same procedure described in refs. [76, 77], then we take all allowed Lorentz invariant contractions with DM bilinears in eq. (2.4).

The first operators to look for are at dimension 5, which implies that we need gauge invariant SM operators $\mathcal{O}_{\alpha\text{SM}}^{(2)}$ with mass dimension 2. The following options are available

$$\mathcal{O}_{\alpha\text{SM}}^{(2)} = \{ H^\dagger H, B_{\mu\nu}, \epsilon_{\mu\nu\rho\sigma}B^{\rho\sigma} \}, \quad (2.6)$$

where H and $B_{\mu\nu}$ are the Higgs doublet and the hypercharge field strength, respectively. The Lorentz invariant combinations with DM bilinears are listed in table 2. Since they are the lowest dimensional non-renormalizable operators, they do not mix onto other ones. As is well known, the resulting long-range interaction arising from the dipole operators severely constrain their Wilson coefficients [78–80]. The dimension 5 Higgs portal operator induces interactions with the gluon field strength once heavy quarks are integrated out [81], and current experiments are probing cross sections in its typical range [82–86]. DM interactions

¹For effective operators up to dimension 6 and neglecting velocity suppressed effects this is a complete basis.

Symbol	Operator	Symbol	Operator	Symbol	Operator
$\mathcal{O}_{\Gamma q}^{(i)}$	$\bar{\chi}\Gamma^\mu\chi\bar{q}_L^i\gamma_\mu q_L^i$	$\mathcal{O}_{\Gamma l}^{(i)}$	$\bar{\chi}\Gamma^\mu\chi\bar{l}_L^i\gamma_\mu l_L^i$	$\mathcal{O}_{\Gamma H}^{(i)}$	$\bar{\chi}\Gamma^\mu\chi H^\dagger i\overleftrightarrow{D}_\mu H$
$\mathcal{O}_{\Gamma u}^{(i)}$	$\bar{\chi}\Gamma^\mu\chi\bar{u}_R^i\gamma_\mu u_R^i$	$\mathcal{O}_{\Gamma e}^{(i)}$	$\bar{\chi}\Gamma^\mu\chi\bar{e}_R^i\gamma_\mu e_R^i$		
$\mathcal{O}_{\Gamma d}^{(i)}$	$\bar{\chi}\Gamma^\mu\chi\bar{d}_R^i\gamma_\mu d_R^i$				

Table 3. Basis of dimension 6 operators for the SM_χ EFT. The first two columns have three different replicas, corresponding to the SM generations. We consider a generic $\bar{\chi}\Gamma^\mu\chi$, which can be either a vector ($\Gamma^\mu = \gamma^\mu$) or an axial ($\Gamma^\mu = \gamma^\mu\gamma^5$) DM current or any linear combination of them.

to the Higgs also yields mono-Higgs events at colliders [87–89], and for light enough DM ($m_\chi < m_h/2$) they contribute to the invisible Higgs decay width [90–93]. No interesting mixing takes place in this dimension 5 sector [68], and for this reason our RG analysis will focus on dimension 6 operators, which we now identify.

For dimension 6 operators, the relevant SM structures of dimension 3 are the currents

$$\mathcal{O}_{\alpha\text{SM}}^{(3)} = \left\{ \bar{q}_L^i\gamma_\mu q_L^i, \bar{u}_R^i\gamma_\mu u_R^i, \bar{d}_R^i\gamma_\mu d_R^i, \bar{l}_L^i\gamma_\mu l_L^i, \bar{e}_R^i\gamma_\mu e_R^i, H^\dagger i\overleftrightarrow{D}_\mu H \right\}, \quad (2.7)$$

where we do not assume any flavor violation. The index i runs over the three different fermion generations, thus the above vector has $5 \times 3 + 1 = 16$ components. The double-arrow derivative entering the Higgs current reads

$$H^\dagger \overleftrightarrow{D}_\mu H \equiv H^\dagger (D_\mu H) - (D_\mu H^\dagger) H, \quad (2.8)$$

with the covariant derivative defined as in eq. (A.3) of appendix A.1.

Lorentz invariant operators can be obtained by contracting the currents in eq. (2.7) with a DM current $\bar{\chi}\Gamma^\mu\chi$, where both vector $\Gamma^\mu = \gamma^\mu$ and axial $\Gamma^\mu = \gamma^\mu\gamma^5$ currents are possible. This gives a total of $16 \times 2 = 32$ independent operators. However, since χ is a singlet, the DM current $\bar{\chi}\Gamma^\mu\chi$ is invariant under RG evolution, thus we can study two 16-dimensional sectors separately. The basis for dimension 6 operators with a specific DM current $\bar{\chi}\Gamma^\mu\chi$ is shown in table 3. For future convenience, we introduce a 16-dimensional vector of Wilson coefficients

$$\mathcal{C}_{\text{SM}_\chi}^T \equiv \left(c_{\Gamma q}^{(1)} \ c_{\Gamma u}^{(1)} \ c_{\Gamma d}^{(1)} \ \Big| \ c_{\Gamma l}^{(1)} \ c_{\Gamma e}^{(1)} \ \Big| \ c_{\Gamma q}^{(2)} \ c_{\Gamma u}^{(2)} \ c_{\Gamma d}^{(2)} \ \Big| \ c_{\Gamma l}^{(2)} \ c_{\Gamma e}^{(2)} \ \Big| \ c_{\Gamma q}^{(3)} \ c_{\Gamma u}^{(3)} \ c_{\Gamma d}^{(3)} \ \Big| \ c_{\Gamma l}^{(3)} \ c_{\Gamma e}^{(3)} \ \Big\| \ c_{\Gamma H} \right), \quad (2.9)$$

where c_α is associated with the operator \mathcal{O}_α in table 3. The solid double line divides DM interactions with the Higgs from the ones with SM fermions. The solid single lines divide different SM generations and within each generation quarks and leptons are divided by a dashed line.

We stress that the dimension 6 operator

$$\mathcal{O}_{\Gamma B} = g' \frac{c_B}{\Lambda^2} \bar{\chi}\Gamma^\mu\chi \partial^\nu B_{\nu\mu} \quad (2.10)$$

does not need to be included in our list since it can be expressed as a linear combination of the ones listed in table 3 by using classical equation of motion [94] for the hypercharge

	u^i	d^i	e^i
$SU(3)_c$	3	3	1
$U(1)_{em}$	+2/3	-1/3	-1

Table 4. SM matter fields and their gauge quantum numbers in the broken phase. In this case q^i , u^i and e^i are Dirac fermions. The index $i = 1, 2, 3$ runs over the three different generations. The top quark (i.e. u^3) is not included.

field strength (see eq. (A.10)). More specifically, the effect of this operator can be absorbed into the following shifts of the Wilson coefficients

$$c_{\Gamma q}^{(i)} \rightarrow c_{\Gamma q}^{(i)} - g'^2 y_q c_B, \quad (2.11)$$

$$c_{\Gamma u}^{(i)} \rightarrow c_{\Gamma u}^{(i)} - g'^2 y_u c_B, \quad (2.12)$$

$$c_{\Gamma d}^{(i)} \rightarrow c_{\Gamma d}^{(i)} - g'^2 y_d c_B, \quad (2.13)$$

$$c_{\Gamma l}^{(i)} \rightarrow c_{\Gamma l}^{(i)} - g'^2 y_l c_B, \quad (2.14)$$

$$c_{\Gamma e}^{(i)} \rightarrow c_{\Gamma e}^{(i)} - g'^2 y_e c_B, \quad (2.15)$$

$$c_H \rightarrow c_H - g'^2 y_H c_B. \quad (2.16)$$

2.2 EMSM $_\chi$ effective theory

The construction of the operator basis for the EMSM $_\chi$ EFT is analogous. The Lagrangian reads

$$\mathcal{L}_{\text{EMSM}_\chi} = \mathcal{L}_{\text{EMSM}} + \bar{\chi}(i\not{\partial} - m_\chi)\chi + \sum_{d>4} \sum_{\alpha} \frac{c_\alpha^{(d)}}{\Lambda^{d-4}} \mathcal{O}_\alpha^{(d)}. \quad (2.17)$$

Details and conventions for the renormalizable EMSM part can be found in appendix A.2. Since matter fields fill vector-like representations of the gauge group in this phase, we employ the set of Dirac fermions

$$\mathcal{F}_{\text{EMSM}} = \{u^i, d^i, e^i\}. \quad (2.18)$$

The index i runs again over the three different SM generations, but this time without the top quark (i.e. without $u^{(3)}$). Gauge quantum numbers are assigned as in table 4. The effective operators are still of the form

$$\mathcal{O}_\alpha^{(d)} = \mathcal{O}_{\alpha\chi}^{(3)} \times \mathcal{O}_{\alpha\text{EMSM}}^{(d-3)}, \quad (2.19)$$

with DM bilinears listed in eq. (2.4).

For dimension 5 operators we only have interactions with the electromagnetic field, i.e.

$$\mathcal{O}_{\alpha\text{EMSM}}^{(2)} = \{F_{\mu\nu}, \epsilon_{\mu\nu\rho\sigma} F^{\rho\sigma}\}, \quad (2.20)$$

and the Lorentz invariant contractions with DM bilinears are listed in table 5. For dimension 6 operators we have the SM currents

$$\mathcal{O}_{\alpha\text{EMSM}}^{(3)} = \{\bar{u}^i \gamma_\mu u^i, \bar{u}^i \gamma_\mu \gamma_5 u^i, \bar{d}^i \gamma_\mu d^i, \bar{d}^i \gamma_\mu \gamma_5 d^i, \bar{e}^i \gamma_\mu e^i, \bar{e}^i \gamma_\mu \gamma_5 e^i\}. \quad (2.21)$$

Symbol	Operator
\mathcal{O}_{MF}	$\bar{\chi}\sigma^{\mu\nu}\chi F_{\mu\nu}$
\mathcal{O}_{EF}	$\bar{\chi}\sigma^{\mu\nu}\chi\epsilon_{\mu\nu\rho\sigma}F^{\rho\sigma}$

Table 5. Basis of dimension 5 operators for the EMSM $_{\chi}$ Effective Theory.

Symbol	Operator	Symbol	Operator	Symbol	Operator
$\mathcal{O}_{\Gamma Vu}^{(i)}$	$\bar{\chi}\Gamma^{\mu}\chi\bar{u}^i\gamma_{\mu}u^i$	$\mathcal{O}_{\Gamma Vd}^{(i)}$	$\bar{\chi}\Gamma^{\mu}\chi\bar{d}^i\gamma_{\mu}d^i$	$\mathcal{O}_{\Gamma Ve}^{(i)}$	$\bar{\chi}\Gamma^{\mu}\chi\bar{e}^i\gamma_{\mu}e^i$
$\mathcal{O}_{\Gamma Au}^{(i)}$	$\bar{\chi}\Gamma^{\mu}\chi\bar{u}^i\gamma_{\mu}\gamma_5u^i$	$\mathcal{O}_{\Gamma Ad}^{(i)}$	$\bar{\chi}\Gamma^{\mu}\chi\bar{d}^i\gamma_{\mu}\gamma_5d^i$	$\mathcal{O}_{\Gamma Ae}^{(i)}$	$\bar{\chi}\Gamma^{\mu}\chi\bar{e}^i\gamma_{\mu}\gamma_5e^i$

Table 6. Basis of dimension 6 operators for the EMSM $_{\chi}$ Effective Theory. Each operator has three different replicas, corresponding to the three SM generations. The DM bilinear can have both vector or axial currents, namely $\Gamma = \{V, A\}$, where $V^{\mu} = \gamma^{\mu}$ and $A^{\mu} = \gamma^{\mu}\gamma_5$.

The top quark is not in the spectrum, thus we count $6 \times 3 - 2 = 16$ independent currents. Also in this case they can be contracted with either a vector or an axial DM current, giving a total of 32 independent operators. Each 16 dimensional sector shown in table 6 can be studied separately. In analogy to eq. (2.9), we define the vector

$$c_{\text{EMSM}_{\chi}}^T = \left(c_{\Gamma Vu}^{(1)} c_{\Gamma Vd}^{(1)} c_{\Gamma Vu}^{(2)} c_{\Gamma Vd}^{(2)} c_{\Gamma Vd}^{(3)} \mid c_{\Gamma Ve}^{(1)} c_{\Gamma Ve}^{(2)} c_{\Gamma Ve}^{(3)} \parallel c_{\Gamma Au}^{(1)} c_{\Gamma Ad}^{(1)} c_{\Gamma Au}^{(2)} c_{\Gamma Ad}^{(2)} c_{\Gamma Ad}^{(3)} \mid c_{\Gamma Ae}^{(1)} c_{\Gamma Ae}^{(2)} c_{\Gamma Ae}^{(3)} \right). \quad (2.22)$$

Here, the solid double line is used to divide DM couplings to a vector or an axial SM current, whereas single solid lines divide quarks from leptons.

The redundant dimension 6 operator in this case is

$$\mathcal{O}_{\Gamma F} = e \frac{c_F}{\Lambda^2} \bar{\chi}\Gamma^{\mu}\chi\partial^{\nu}F_{\nu\mu}. \quad (2.23)$$

Equations of motion for the electromagnetic field strength (see eq. (A.12)) translates this operator into a linear combination of the ones listed in table 6, which equivalently amounts to this shift of the Wilson coefficients for the operators with SM vector currents

$$c_{\Gamma Vu}^{(i)} \rightarrow c_{\Gamma Vu}^{(i)} - e^2 Q_u c_F, \quad (2.24)$$

$$c_{\Gamma Vd}^{(i)} \rightarrow c_{\Gamma Vd}^{(i)} - e^2 Q_d c_F, \quad (2.25)$$

$$c_{\Gamma Ve}^{(i)} \rightarrow c_{\Gamma Ve}^{(i)} - e^2 Q_e c_F. \quad (2.26)$$

The operators with SM axial currents are not affected, since the photon only couples to vector currents.

2.3 Matching the two EFTs at the EWSB scale

We conclude this section by giving matching conditions between the two theories, namely the relations between the Wilson coefficients in eq. (2.22) and those in eq. (2.9), both evaluated at the EWSB scale, which is smaller than Λ in this setup. As we will see shortly, the leading contribution arises already at tree level, therefore we do not need to consider the subleading one-loop contributions.

When performing the tree-level matching, going from left- and right-handed currents to vector and axial currents is straightforward. But this is not the full story, since the operator coupling the DM to the Higgs current leads to the following contribution obtained by giving the Higgs doublets an EWSB VEV. The result is to induce an effective tree-level coupling between the DM and the Z boson

$$\mathcal{L}_{\chi\chi Z} = \frac{c_H}{\Lambda^2} \bar{\chi} \Gamma^\mu \chi \langle H^\dagger \rangle i \overleftrightarrow{D}_\mu \langle H \rangle = -\frac{c_H}{\Lambda^2} v^2 \sqrt{g^2 + g'^2} \bar{\chi} \Gamma^\mu \chi Z_\mu. \quad (2.27)$$

The Z boson also couples to SM fermions

$$\mathcal{L}_{\text{N.C.}}^Z = \frac{g}{2c_w} Z_\mu J_0^\mu, \quad (2.28)$$

where the neutral current J_0^μ is defined as follows

$$J_0^\mu = \sum_f [g_{Vf} \bar{f} \gamma^\mu f + g_{Af} \bar{f} \gamma^\mu \gamma^5 f], \quad (2.29)$$

$$g_{Vf} = T_f^3 - 2s_w^2 Q_f, \quad (2.30)$$

$$g_{Af} = -T_f^3. \quad (2.31)$$

Here, T_f^3 is the third component of the weak isospin, s_w the sine of the weak mixing angle and Q_f the fermion electromagnetic charge. The coefficients for the SM fermions explicitly read

$$\begin{aligned} g_{Vu} &= \frac{1}{2} - \frac{4}{3}s_w^2, & g_{Vd} &= -\frac{1}{2} + \frac{2}{3}s_w^2, & g_{Ve} &= -\frac{1}{2} + 2s_w^2, \\ g_{Au} &= -\frac{1}{2}, & g_{Ad} &= \frac{1}{2}, & g_{Ae} &= \frac{1}{2}. \end{aligned} \quad (2.32)$$

Integrating out the Z boson gives rise to the Fermi Lagrangian for SM neutral currents

$$\mathcal{L}_{\text{Fermi}} = -\frac{G_F}{\sqrt{2}} J_0^\mu J_{0\mu}. \quad (2.33)$$

Analogously, tree-level Z exchange gives a finite threshold corrections to the Wilson coefficients of the EMSM_χ EFT. The complete matching conditions read

$$c_{\Gamma Vu}^{(i)} = \frac{c_{\Gamma q}^{(i)} + c_{\Gamma u}^{(i)}}{2} + c_H g_{Vu}, \quad (2.34)$$

$$c_{\Gamma Vd}^{(i)} = \frac{c_{\Gamma q}^{(i)} + c_{\Gamma d}^{(i)}}{2} + c_H g_{Vd}, \quad (2.35)$$

$$c_{\Gamma Ve}^{(i)} = \frac{c_{\Gamma l}^{(i)} + c_{\Gamma e}^{(i)}}{2} + c_H g_{Ve}, \quad (2.36)$$

$$c_{\Gamma Au}^{(i)} = \frac{-c_{\Gamma q}^{(i)} + c_{\Gamma u}^{(i)}}{2} + c_H g_{Au}, \quad (2.37)$$

$$c_{\Gamma Ad}^{(i)} = \frac{-c_{\Gamma q}^{(i)} + c_{\Gamma d}^{(i)}}{2} + c_H g_{Ad}, \quad (2.38)$$

$$c_{\Gamma Ae}^{(i)} = \frac{-c_{\Gamma l}^{(i)} + c_{\Gamma e}^{(i)}}{2} + c_H g_{Ae}. \quad (2.39)$$

Figure 2. External legs corrections for SM fermions.

Figure 3. External legs for SM Higgs.

3 Renormalization group evolution

We present the complete one-loop RG equations in both EFTs. Here, we only show Feynman diagrams and quote final results. Regularization and renormalization at one loop in both EFTs are detailedly discussed in appendix B. As explained in the previous section, no interesting loop effect takes place among the dimension 5 operators, besides the well known heavy quark threshold contribution from the Higgs portal [81]. Thus we focus on dimension 6 operators.

3.1 From the messenger scale to the EWSB scale

The evolution of the Wilson coefficients in eq. (2.9) is described by the differential equation

$$\frac{d\mathcal{C}_{\text{SM}_\chi}}{d\ln\mu} = \gamma_{\text{SM}_\chi}\mathcal{C}_{\text{SM}_\chi}, \quad (3.1)$$

where μ is the renormalization scale and γ_{SM_χ} is the anomalous dimension matrix. Our goal here is to fill out the $16 \times 16 = 256$ entries of the matrix γ_{SM_χ} .

We start our one-loop analysis in this theory by considering external legs corrections. Since the DM field is a gauge singlet, these contributions only involve SM fields and interactions. We perform the field renormalizations

$$\psi_i \rightarrow Z_{\psi_i}^{1/2}\psi_i, \quad H \rightarrow Z_H^{1/2}H, \quad (3.2)$$

where ψ_i is any SM fermion, and we do it in such a way to subtract the infinite part from the residue of each one-loop propagator. There are only two possible sources for this effect, which are gauge and Yukawa interactions. As is well known, the Higgs quartic coupling does not induce a one-loop contribution to the wave-function renormalization. The relevant Feynman diagrams are shown in figures 2 and 3 for fermion and Higgs fields, respectively.

When considering vertex corrections, one still has to deal only with these two interactions. We organize the presentation by fixing the external legs of a specific amplitude,

Figure 4. One loop corrections to the Wilson coefficient c_L in the SM_χ EFT, where the crossed circle denotes the effective vertex between SM fields and the DM bilinear. The index j for right-handed fermions can be either u or d . The diagrams for the one-loop corrections to c_R^u and c_R^d are analogous, but without the W_μ^i gauge bosons in the loop.

Figure 5. One loop corrections to the Wilson coefficient c_H in the SM_χ EFT. The crossed circle notation is the same as figure 4. In the first row we have corrections from gauge interactions, in the second row from Yukawa interactions.

and then identifying all the possible one-loop contributions. In other words, we fix a given effective operator from the ones in table 6 and then look for operators mixing into it.

We start from the loop corrections to the Wilson coefficient c_L , which can be induced by gauge interactions (diagonal renormalization) and by Yukawa interactions (off-diagonal renormalization). The associated Feynman diagrams are shown in figure 4. Loop effects for c_R^u and c_R^d are analogous, with the important difference that right-handed fermions have no $SU(2)_L$ interactions, and therefore there are no diagrams with W_μ^i in the loop.

The analysis of loop corrections to c_H involves many more Feynman diagrams. The associated operator describes the DM interaction with two Higgs bosons, and we expect by gauge invariance also diagrams with two Higgses and one electroweak gauge boson. We have computed all the possible one-loop diagrams, both the ones with only two Higgs fields on the external legs and the ones with an additional W_μ^i or a B_μ gauge boson on the external legs, and checked that they combine in a gauge invariant way to give the Higgs current defined in eq. (2.8). We show in figure 5 only the diagrams with two external Higgs bosons, which get contributions from gauge and Yukawa interactions. For the latter, we

Figure 6. One loop corrections to the Wilson coefficient c_B of the redundant operator in the SM_χ EFT. The crossed circle notation is the same as figure 4.

checked that the associated diagrams with an external B_μ combine in a gauge invariant way with the others only after using the SM hypercharge values, as it should be.

Finally, loop diagrams in figure 6 radiatively induce a contribution to the Wilson coefficient c_B of the redundant operator in eq. (2.10). By consistently using the equation of motion, this translates into a shift for the independent operators as in eqs. (2.11)–(2.16).²

The explicit expression for the one-loop amplitudes, as well as the consequent derivation of the RG equations, are presented in appendix B.1. As shown there, the gauge interactions contribution to wave-function renormalization exactly cancels with the associated vertex corrections. This is consistent with the Ward identities in abelian gauge theories, and with the fact that non-abelian gauge interactions renormalize only axial currents starting at two loops. The final anomalous dimension matrix has two main pieces

$$\gamma_{SM_\chi} = \gamma_{SM_\chi}|_\lambda + \gamma_{SM_\chi}|_Y, \tag{3.3}$$

where the contribution proportional to the hypercharge gauge couplings is a consequence of the diagrams in figure 6. The explicit expressions read

$$\gamma_{SM_\chi}|_\lambda = \frac{1}{8\pi^2} \begin{pmatrix} (\lambda_u^2 + \lambda_d^2)/2 - \lambda_u^2/2 - \lambda_d^2/2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & (\lambda_u^2 + \lambda_d^2)/2 \\ -\lambda_u^2 & \lambda_u^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_u^2 \\ -\lambda_d^2 & 0 & \lambda_d^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_d^2 \\ \hline 0 & 0 & 0 & \lambda_e^2/2 - \lambda_e^2/2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_e^2/2 \\ 0 & 0 & 0 & -\lambda_e^2 & \lambda_e^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_e^2 \\ \hline 0 & 0 & 0 & 0 & 0 & (\lambda_c^2 + \lambda_s^2)/2 - \lambda_c^2/2 - \lambda_s^2/2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & (\lambda_c^2 + \lambda_s^2)/2 \\ 0 & 0 & 0 & 0 & 0 & -\lambda_c^2 & \lambda_c^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_c^2 \\ 0 & 0 & 0 & 0 & 0 & -\lambda_s^2 & 0 & \lambda_s^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_s^2 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_\mu^2/2 - \lambda_\mu^2/2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_\mu^2/2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -\lambda_\mu^2 & \lambda_\mu^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_\mu^2 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & (\lambda_t^2 + \lambda_b^2)/2 - \lambda_t^2/2 - \lambda_b^2/2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & (\lambda_t^2 + \lambda_b^2)/2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -\lambda_t^2 & \lambda_t^2 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_t^2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -\lambda_b^2 & 0 & \lambda_b^2 & 0 & 0 & 0 & 0 & 0 & \lambda_b^2 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \lambda_\tau^2/2 - \lambda_\tau^2/2 & 0 & 0 & 0 & 0 & \lambda_\tau^2/2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -\lambda_\tau^2 & \lambda_\tau^2 & 0 & 0 & 0 & \lambda_\tau^2 \\ \hline 3(\lambda_u^2 - \lambda_d^2) & -3\lambda_u^2 & 3\lambda_d^2 & -\lambda_e^2 & \lambda_e^2 & 3(\lambda_c^2 - \lambda_s^2) & -3\lambda_c^2 & 3\lambda_s^2 & -\lambda_\mu^2 & \lambda_\mu^2 & 3(\lambda_t^2 - \lambda_b^2) & -3\lambda_t^2 & 3\lambda_b^2 & -\lambda_\tau^2 & \lambda_\tau^2 & 3\sum_q \lambda_q^2 + \sum_l \lambda_l^2 & 0 & 0 & 0 \end{pmatrix}, \tag{3.4}$$

²Alternatively, instead of dealing with a redundant operator, we can restrict ourselves to a minimal basis. In this case one has to compute one-loop corrections to Wilson coefficients coming from one-particle-reducible (penguin-type) diagrams. We explicitly checked that the two procedures lead to the same results, as it should be.

Figure 7. Vertex corrections in the EMSM_χ EFT induced by SM four-fermion interactions.

for the Yukawa contribution, and

$$\gamma_{\text{SM}_\chi}^Y = \frac{4}{3} \frac{g'^2}{16\pi^2} \begin{pmatrix} \begin{array}{c|c|c|c|c} 6y_q^2 & 3y_q y_u & 3y_q y_d & 2y_q y_l & y_q y_e \\ 6y_u y_q & 3y_u^2 & 3y_u y_d & 2y_u y_l & y_u y_e \\ 6y_d y_q & 3y_d y_u & 3y_d^2 & 2y_d y_l & y_d y_e \\ 6y_l y_q & 3y_l y_u & 3y_l y_d & 2y_l^2 & y_l y_e \\ 6y_e y_q & 3y_e y_u & 3y_e y_d & 2y_e y_l & y_e^2 \end{array} & \begin{array}{c|c|c|c|c} 6y_q^2 & 3y_q y_u & 3y_q y_d & 2y_q y_l & y_q y_e \\ 6y_u y_q & 3y_u^2 & 3y_u y_d & 2y_u y_l & y_u y_e \\ 6y_d y_q & 3y_d y_u & 3y_d^2 & 2y_d y_l & y_d y_e \\ 6y_l y_q & 3y_l y_u & 3y_l y_d & 2y_l^2 & y_l y_e \\ 6y_e y_q & 3y_e y_u & 3y_e y_d & 2y_e y_l & y_e^2 \end{array} & \begin{array}{c|c|c|c|c} 6y_q^2 & 3y_q y_u & 3y_q y_d & 2y_q y_l & y_q y_e \\ 6y_u y_q & 3y_u^2 & 3y_u y_d & 2y_u y_l & y_u y_e \\ 6y_d y_q & 3y_d y_u & 3y_d^2 & 2y_d y_l & y_d y_e \\ 6y_l y_q & 3y_l y_u & 3y_l y_d & 2y_l^2 & y_l y_e \\ 6y_e y_q & 3y_e y_u & 3y_e y_d & 2y_e y_l & y_e^2 \end{array} & \begin{array}{c|c|c|c|c} 6y_q^2 & 3y_q y_u & 3y_q y_d & 2y_q y_l & y_q y_e \\ 6y_u y_q & 3y_u^2 & 3y_u y_d & 2y_u y_l & y_u y_e \\ 6y_d y_q & 3y_d y_u & 3y_d^2 & 2y_d y_l & y_d y_e \\ 6y_l y_q & 3y_l y_u & 3y_l y_d & 2y_l^2 & y_l y_e \\ 6y_e y_q & 3y_e y_u & 3y_e y_d & 2y_e y_l & y_e^2 \end{array} & \begin{array}{c|c|c|c|c} 6y_q^2 & 3y_q y_u & 3y_q y_d & 2y_q y_l & y_q y_e \\ 6y_u y_q & 3y_u^2 & 3y_u y_d & 2y_u y_l & y_u y_e \\ 6y_d y_q & 3y_d y_u & 3y_d^2 & 2y_d y_l & y_d y_e \\ 6y_l y_q & 3y_l y_u & 3y_l y_d & 2y_l^2 & y_l y_e \\ 6y_e y_q & 3y_e y_u & 3y_e y_d & 2y_e y_l & y_e^2 \end{array} & \begin{array}{c|c|c|c|c} 6y_q^2 & 3y_q y_u & 3y_q y_d & 2y_q y_l & y_q y_e \\ 6y_u y_q & 3y_u^2 & 3y_u y_d & 2y_u y_l & y_u y_e \\ 6y_d y_q & 3y_d y_u & 3y_d^2 & 2y_d y_l & y_d y_e \\ 6y_l y_q & 3y_l y_u & 3y_l y_d & 2y_l^2 & y_l y_e \\ 6y_e y_q & 3y_e y_u & 3y_e y_d & 2y_e y_l & y_e^2 \end{array} & \begin{array}{c|c|c|c|c} 6y_H y_q & 3y_H y_u & 3y_H y_d & 2y_H y_l & y_H y_e \\ 6y_H y_q & 3y_H y_u & 3y_H y_d & 2y_H y_l & y_H y_e \\ 6y_H y_q & 3y_H y_u & 3y_H y_d & 2y_H y_l & y_H y_e \\ 6y_H y_q & 3y_H y_u & 3y_H y_d & 2y_H y_l & y_H y_e \\ 6y_H y_q & 3y_H y_u & 3y_H y_d & 2y_H y_l & y_H y_e \end{array} \end{pmatrix}, \quad (3.5)$$

with the hypercharges as in eq. (B.7).

3.2 From the EWSB scale to the nuclear scale

The Wilson coefficients given in eq. (2.22) for the EFT below the EWSB scale evolve according to

$$\frac{d\mathcal{C}_{\text{EMSM}_\chi}}{d \ln \mu} = \gamma_{\text{EMSM}_\chi} \mathcal{C}_{\text{EMSM}_\chi}. \quad (3.6)$$

We now discuss how to obtain the 16×16 anomalous dimension matrix $\gamma_{\text{EMSM}_\chi}$. The external leg corrections only come from the gauge sector. For strong interactions they are identical to the ones in the SM_χ EFT, and for electromagnetic interactions they can be easily obtained from the analogous hypercharge diagrams. Their effect is again to cancel out against the associated vertex corrections.

Also in this case there are two classes of vertex corrections. The first ones are due to the SM four-fermion interactions, in the way we show in figure 7. This diagram in the EMSM_χ EFT is the analogous of the correction to c_H discussed in the SM_χ EFT, but the Z boson is integrated out in this phase of the theory. Despite the fact that these diagrams are suppressed by the Fermi constant, we keep them to be consistent with the analysis above the EWSB scale, since their contribution is proportional to $G_F m_\psi^2 \propto \lambda_\psi^2$.

The second effect is the radiative correction to the Wilson coefficient c_F of the redundant operator in eq. (2.23). The diagrams are analogous to the fermion loop in figure 6,

4 Applications to spin-independent searches

In section 3 we presented the full 16×16 anomalous dimension matrices describing the one-loop RG evolution for dimension 6 operators above and below the EWSB scale. As promised in the introduction, these details can be skipped by a reader only interested in our final results. For the benefit of such a reader, we now briefly summarize the RG procedure.

The boundary conditions for the RG system are the SM_χ EFT Wilson coefficients at the cutoff Λ . In a generic UV complete model with mediators heavier than the weak scale, they are obtained by integrating out the mediator fields. Then we evolve them down to the EWSB scale, which we take equal to the Z boson mass. It is convenient to introduce the following dimensionless variable related to the renormalization scale μ ,

$$t \equiv \ln \left[\frac{\mu}{m_Z} \right]. \quad (4.1)$$

In this notation the matching is performed at $t = 0$, whereas the Wilson coefficient c_Λ are specified at the cutoff scale, $t_\Lambda = \ln[\Lambda/m_Z]$. The RG evolution in the SM_χ EFT is obtained by solving the system of differential equations

$$\frac{d\mathcal{C}_{\text{SM}_\chi}}{dt} = \gamma_{\text{SM}_\chi} \mathcal{C}_{\text{SM}_\chi}, \quad 0 \leq t \leq t_\Lambda, \quad (4.2)$$

$$\mathcal{C}_{\text{SM}_\chi}(t_\Lambda) = c_\Lambda, \quad (4.3)$$

with the Wilson coefficients vector $\mathcal{C}_{\text{SM}_\chi}$ defined in eq. (2.9), and the explicitly expression for the anomalous dimension matrix γ_{SM_χ} given in section 3.1. Once at $t = 0$, we perform the matching between the two theories as described in section 2.3. The subsequent RG evolution for the Wilson coefficients $\mathcal{C}_{\text{EMSM}_\chi}$ defined in eq. (2.22) is described by

$$\frac{d\mathcal{C}_{\text{EMSM}_\chi}}{dt} = \gamma_{\text{EMSM}_\chi} \mathcal{C}_{\text{EMSM}_\chi}, \quad t_N \leq t \leq 0, \quad (4.4)$$

with the explicit $\gamma_{\text{EMSM}_\chi}$ given in section 3.2 and $t_N = \ln[1 \text{ GeV}/m_Z] \simeq -4.51$. The outcome of this three-step procedure is the array of Wilson coefficients at the nuclear scale c_N . We only perform linear operations on the Wilson coefficients, therefore we have

$$c_N = U_\Lambda c_\Lambda. \quad (4.5)$$

The Λ -dependent evolution matrix U_Λ is derived in appendix C and for a user-friendly recipe we refer to appendix D.

The rest of this section is devoted to applying eq. (4.5) to limits from direct detection experiments. We focus on spin-independent searches, since they have much stronger bounds, and this has two implications. First, we need to consider effective operators with DM vector currents $\bar{\chi}\gamma^\mu\chi$. For pure elastic scattering this operator is non vanishing only for Dirac fermions, but our results are also valid for inelastic scattering of two splitted Majorana states [95]. Second, matrix elements of SM fermion currents have only contributions from valence quarks in the target nuclei, therefore the direct detection cross section at zero momentum transfer and low DM velocities reads

$$\sigma_{\mathcal{N}}^{\text{SI}} = \frac{m_\chi^2 m_{\mathcal{N}}^2}{(m_\chi + m_{\mathcal{N}})^2 \pi \Lambda^4} |c_{V V u}^{(1)}(A + Z) + c_{V V d}^{(1)}(2A - Z)|^2. \quad (4.6)$$

Here, $c_{VVu}^{(1)}$ and $c_{VVd}^{(1)}$ are the first two component of the vector defined in eq. (2.22), whereas A , Z and $m_{\mathcal{N}}$ are the mass number, atomic number and mass of the target nucleus \mathcal{N} , respectively.

In what follows, we consider specific choices of Wilson coefficients c_{Λ} at the cutoff scale and we evolve them down to the nuclear scale as in eq. (4.5). The running of the Yukawa couplings above the EWSB scale is performed according to ref. [96] and of the quark masses below m_Z using the results in ref. [97]. We compare the predicted rate as in eq. (4.6) to the experimental limits, and extract bounds on the Wilson coefficients. Our results are model independent, in the sense that every UV complete model generating that specific set c_{Λ} when matched on the SM_{χ} is subject to our constraints.

4.1 D5 and D7 operators

The connection between different DM negative searches is often expressed in terms of limits on the coefficients for the effective operators introduced in ref. [25]. For a vector current of a fermion WIMP, the relevant operators involving quarks are

$$\mathcal{L}_{D5} = \frac{c_{D5}}{\Lambda^2} \bar{\chi} \gamma^{\mu} \chi \left[\sum_i \bar{u}^i \gamma_{\mu} u^i + \sum_i \bar{d}^i \gamma_{\mu} d^i \right], \tag{4.7}$$

$$\mathcal{L}_{D7} = \frac{c_{D7}}{\Lambda^2} \bar{\chi} \gamma^{\mu} \chi \left[\sum_i \bar{u}^i \gamma_{\mu} \gamma_5 u^i + \sum_i \bar{d}^i \gamma_{\mu} \gamma_5 d^i \right]. \tag{4.8}$$

We now connect this description to the notation used in this paper, and explore the consequences of connecting EFT scales.

Keeping the complementarity among different searches in mind (e.g. between collider and direct searches as in ref. [25]), we take the operators in eqs. (4.7) and (4.8) as defined at the EFT cutoff Λ . In other words these are operators in the SM_{χ} EFT. Considering flavor universal coupling to SM quarks, D5 and D7 are reproduced by this set of Wilson coefficients

$$c_{\Lambda}^T|_{D5,D7} = \left(c_L \ c_R \ c_R, 0 \ 0 | c_L \ c_R \ c_R, 0 \ 0 | c_L \ c_R \ c_R, 0 \ 0 || 0 \right), \tag{4.9}$$

where

$$c_{D5} = \frac{c_L + c_R}{2}, \tag{4.10}$$

$$c_{D7} = \frac{-c_L + c_R}{2}. \tag{4.11}$$

Our results are shown in the four panels of figure 8. In the top-left panel we consider the case where only D5 is switched on, and plot current and projected experimental limits in the (m_{χ}, Λ) plane for $c_{D5} = 1$. As is well known, quite high scales for the mediator masses are necessary to be consistent with experimental exclusion bounds. We gain valuable information from this plot: given the extremely strong constraints on this operator, we are still likely to get useful limits on the scale Λ in other cases where the dominant contribution to direct detection rates is via D5 generated by SM loop effects. We deal with these cases in the next subsections, but we first complete the discussion of the (D5, D7) set.

Figure 8. Experimental limits from direct detection for the D5 and D7 operators. In the top-left (right) panel we consider only D5 (D7) switched on at the scale Λ , and plot the lower bounds on Λ from XENON100 (solid, red) [73] and LUX (solid, blue) [74], as well as projected limits from SCDMS (dot-dashed, green), XENON1T (dot-dashed, purple), DARKSIDE G2 (dot-dashed, magenta), LZ (dot-dashed, brown) [75]. The dotted orange line gives the correct thermal relic density. In the bottom panel we fix m_χ and plot the region allowed by LUX in the (c_{D5}, c_{D7}) plane for three different values of Λ . The faded bands, which only constrain the vector coupling c_{D5} , show the limits which would be obtained ignoring our analysis. We also plot the thermal relic lines whenever they are in the parameter space region under consideration.

The top-right panel of figure 8 shows the analogous case where only D7 is switched on at the scale Λ , with $c_{D7} = 1$. The limits on Λ are weaker than the case of D5, but still in the multi-TeV region [68]. For both D5 and D7 we also plot the line that gives a correct thermal relic density, obtained using the annihilation cross section in ref. [98]. Current limits exclude thermal relics with mass $m_\chi \gtrsim 3$ TeV for D5, with a potential of excluding DM masses of the order of 10 TeV by forthcoming experiments. The weaker limits for D7 are still in the range $m_\chi \gtrsim 200$ GeV, which can be improved to reach TeV masses in the future.

Both upper panels are for either c_5 or c_7 equal to 1. To relax this assumption one cannot just rescale the vertical axis by $\Lambda \rightarrow \Lambda c_i^{-1/2}$. While it is true that the rate in eq. (4.6) scales

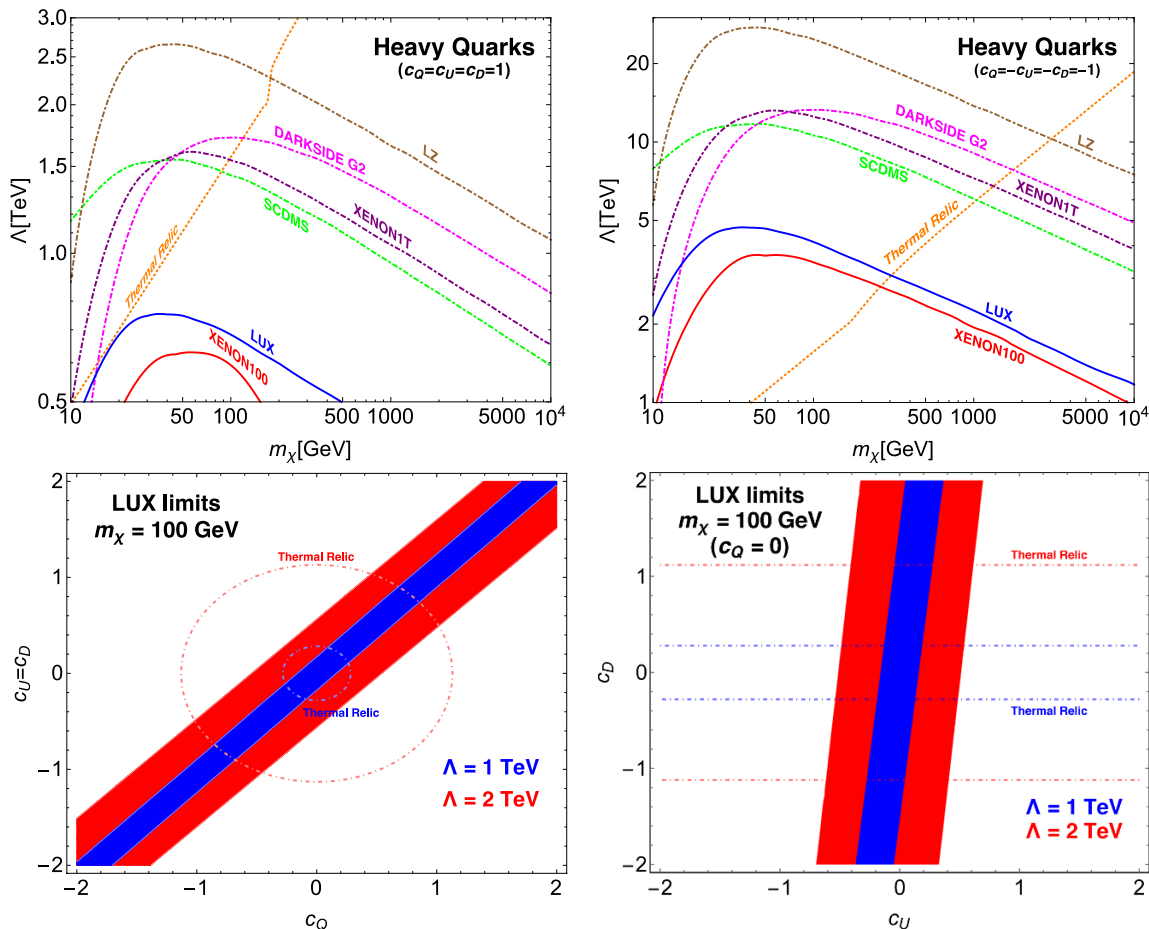

Figure 9. Same as figure 8 but for DM vector current interactions with heavy quarks.

to vector currents. In the bottom-right panel we consider isospin violation by coupling the DM only to right handed quarks (i.e. $c_Q = 0$) and identifying the allowed region in the (c_U, c_D) plane. The bands are close to the vertical line going through $c_U = 0$, since the effect is driven by the top Yukawa.

4.3 Leptophilic dark matter

Another interesting possibility are leptophilic DM models

$$c_{\Lambda}^T|_{\text{Leptoph.}} = \left(0 \ 0 \ 0 \ c_l \ c_e \ 0 \ 0 \ 0 \ c_l \ c_e \ 0 \ 0 \ 0 \ c_l \ c_e \parallel 0 \right), \quad (4.13)$$

where for simplicity we consider flavor universal coupling to leptons. In such models there are many sources of couplings to light quarks currents. The Yukawa coupling of the τ induces a mixing into the Higgs current, which in turn leads to a coupling to light quarks when the Z is integrated out. Hypercharge (electromagnetic) interactions above (below) the EWSB scale also induce mixing onto light quark currents.

Since it turns out that the mixing driven by Yukawa couplings does not lead to any appreciable constraint, the direct detection rate is induced by hypercharge and electromagnetic interactions. As manifest from the explicit matrices in eqs. (3.5) and (3.9), such

Figure 10. Same as figure 8 but for DM vector current interactions with leptons.

a mixing does not affect axial currents, therefore in this case we can only put limits on interactions with vector currents of leptons. This is in contrast with the heavy quarks case, where the limits we found were much stronger for interactions with axial currents. Our results for coupling vector lepton currents to the vector DM current are shown in the left panel of figure 10. The right panel of figure 10 displays the allowed regions in the (c_l, c_e) plane for fixed DM mass and two different values of Λ . Since we do not have here an order one coupling like λ_t , the bands are wider than in the heavy quarks case. We still have the characteristic orientation along a diagonal, although this time along the one described $c_l \sim -c_e$, for the reasons explained above.

4.4 Dimension 6 Higgs portal

The last example we discuss is DM communicating with SM fields only via Higgs couplings

$$c_{\Lambda}^T|_{\text{Higgs}} = \left(0 \ 0 \ 0 \ 0 \ 0 \mid 0 \ 0 \ 0 \ 0 \ 0 \mid 0 \ 0 \ 0 \ 0 \ 0 \mid c_H \right). \quad (4.14)$$

This dimension 6 Higgs portal implies a DM vector current tree-level coupling with the Z boson as a consequence of EWSB, as shown in eq. (2.27). As usual, by evolving the Wilson coefficients to the nuclear scale, we quantify the implications of negative direct searches. In figure 11 we fix $c_H = 1$ and plot the current and projected exclusion limits in the (m_{χ}, Λ) plane, as well as the line giving a thermal relic. The constraints are pretty severe, and future experiments can rule out thermal relics up to masses of the order of 10 TeV. Models with a Z' portal field generate a Wilson coefficient array as in eq. (4.14) if the spin-1 mediator only couples to the SM Higgs. The stringent limits persist in any Z' portal model even if the Z' couples to other SM fields besides the Higgs.

5 Discussion

In the last decade we witnessed an enormous progress by direct searches, which excluded a large parameter space fraction for WIMPs. In particular, models with tree-level vector-vector interactions with light quarks (i.e. D5 in eq. (4.7)) are severely challenged, as shown

Figure 11. Same as figure 8 but for DM vector current interactions with the SM Higgs doublet.

in the left panels of our figure 8. This is not surprising, since spin-independent cross sections arising from tree-level Z boson exchange were ruled out years ago. This effort continues with the new LUX run and with forthcoming experiments, which will soon either discover DM or improve the exclusion limits by one or two orders of magnitude. At the same time, center of mass energies at the LHC will be increased up to a factor of two, and new regions of mass and couplings in DM simplified models will be probed. Last but not least, new generation ground-based and satellite experiments will look for products of DM reactions, constraining the Milky Way WIMPs annihilation rate. We will soon get access to many complementary results on WIMPs property.

When combining the negative outcome of different searches, it is crucial to properly handle the separation among the scales probed by the different experiments. This paper fills the gap between the mediator scales and the nuclear scales for singlet fermion DM models. As sketched in figure 1, we assumed that all non-SM particles (except possibly the DM) are heavier than the weak scale, and we considered the EFT obtained from integrating out these heavy degrees of freedom. It is certainly true that assuming contact interactions with SM fields is not always justified in a collider environment. However, given the typical recoil energy for DM-nucleus scattering, this is always the case for direct searches. Every DM model with mediator fields heavier than the weak scale (possibly constrained by collider or indirect searches) can be matched onto an EFT with only DM interactions with the SM (the SM_χ EFT in figure 1), and the subsequent model-independent one-loop RG evolution properly connects physics at the mediator scales to direct detection observables.

We used a systematic power counting in the suppression scale of the contact effective interactions, and we considered non-renormalizable operators up to dimension 6. Mixing among operators is a standard phenomenon in the dimension 6 sector, where SM interactions mix every operator into all the others. We identified the interactions responsible for these mixings, and computed the associated anomalous dimension matrices. Despite the size of the strong coupling constant α_s , QCD interactions do not play any significant role since SM quark currents are not renormalized at one loop. QCD contributions in

general cannot induce flavor- or parity-violating mixing, and unless there is a cancellation among subamplitudes [22, 61, 65, 66] they can only modify the overall rate by a numerical factor of order one. The RGE in our case was instead driven by Yukawa and electroweak interactions. The former can mix SM fermion currents onto Higgs currents, which in turn generates DM interactions with SM fermion currents once the Z boson is integrated out. The latter mixes every SM current onto all the others. Given this rich mixing structure, for an arbitrary choice of DM interactions we are very likely to radiatively induce the strongly constrained D5 vector-vector operator defined in eq. (4.7), and get significant bounds from experimental results.

In section 4 we discussed applications of our results, focusing on examples where the operator mixing is the main source for direct detection rates. For dimensionless couplings of order one, in most of the cases we found multi-TeV constraints on the mediator mass scale. This rules out a significant region of parameter space where the DM can be a thermal relic, although one can always resort to a non-standard cosmological history [100, 101]. For fixed DM and mediator masses, being consistent with the exclusion limits implies a peculiar alignment among the different dimensionless couplings. Besides the examples discussed here, further singlet fermion DM models generating dimension 6 operators at the mediator scale can be matched onto our framework, and exclusion bounds from direct searches can be derived.

Our work shows how to systematically account for loop effects in fermion singlet DM models. We envision several possible future directions. The next natural step for singlet fermion is to include dimension 7 operators, that are suppressed by an additional power of $1/\Lambda$. These include DM interactions with (pseudo)scalar and tensor currents of SM fermions and with gauge boson field strengths. Interesting mixing effects involving specific operators of this type have already been studied and used to explore the complementarity of direct searches with indirect detection [62] and searches at hadron colliders [64, 69]. Singlet scalar WIMPs belong to a separate chapter, since scalar and vector currents have different mass dimensions, and dimension 6 operators would involve also SM field strengths. Moreover, a singlet scalar WIMP can have renormalizable interactions with SM fields [102].

On a different route, one can apply the results of our paper to simplified models. The operators considered in this work are generated for example by the exchange of a spin-1 mediator. Complementarity among different searches in this class of models have been investigated in refs. [103–106], focusing on parameter space regions with a tree-level direct detection signal. It is interesting to use the setup built in this paper to extend these studies to cases where the dominant effects are given by the operators discussed in section 4, such that the direct detection rate is loop induced. As we eagerly await for new data, and hopefully for a DM discovery, it is important to stress that loop effects extend the notion of complementarity among different DM searches.

A Standard Model: conventions and results

In this appendix we define our conventions and collect useful SM results. Our conventions for the space-time metric, the spinor and gauge fields are the same as in ref. [107].

A.1 Lagrangian in the $SU(3)_c \times SU(2)_L \times U(1)_Y$ phase

Above the EWSB scale the SM has an unbroken $SU(3)_c \times SU(2)_L \times U(1)_Y$ gauge symmetry, and the matter fields shown in table 1. We divide the full Lagrangian into four contributions

$$\mathcal{L}_{\text{SM}} = \mathcal{L}_{\text{YM}} + \mathcal{L}_{\text{fermions}} + \mathcal{L}_{\text{Higgs}} + \mathcal{L}_{\text{Yukawa}}. \quad (\text{A.1})$$

The Lagrangian for the gauge sector read

$$\mathcal{L}_{\text{YM}} = -\frac{1}{4}G^{A\mu\nu}G_{\mu\nu}^A - \frac{1}{4}W^{I\mu\nu}W_{\mu\nu}^I - \frac{1}{4}B^{\mu\nu}B_{\mu\nu}, \quad (\text{A.2})$$

where the indices $A = 1, \dots, 8$ and $I = 1, 2, 3$ run over the adjoint representations of $SU(3)_c$ and $SU(2)_L$, respectively. We define a covariant derivative acting on matter fields as follows

$$D_\mu = \partial_\mu - ig_s \frac{\lambda^A}{2} G_\mu^A - ig \frac{\sigma^I}{2} W_\mu^I - ig' Y B_\mu. \quad (\text{A.3})$$

The Gell-Mann (λ^A) and Pauli (σ^I) matrices act on color and weak-isospin indices (if any), respectively, whereas the hypercharge Y is assigned as in table 1. Then we have

$$\mathcal{L}_{\text{fermions}} = \sum_{i=1}^3 [\bar{q}_L^i i\not{D}q_L^i + \bar{u}_R^i i\not{D}u_R^i + \bar{d}_R^i i\not{D}d_R^i + \bar{l}_L^i i\not{D}l_L^i + \bar{e}_R^i i\not{D}e_R^i], \quad (\text{A.4})$$

$$\mathcal{L}_{\text{Higgs}} = (D^\mu H)^\dagger (D_\mu H) + \mu^2 H^\dagger H - \lambda (H^\dagger H)^2. \quad (\text{A.5})$$

Finally, the Yukawa couplings between fermions and the Higgs doublet are

$$\mathcal{L}_{\text{Yukawa}} = -\lambda_{u^{(i)}} \bar{q}_L^i \tilde{H} u_R^i - \lambda_{d^{(i)}} \bar{q}_L^i H d_R^i - \lambda_{e^{(i)}} \bar{l}_L^i H e_R^i + \text{h.c.}, \quad \tilde{H} = \epsilon H^*. \quad (\text{A.6})$$

For the purpose of this work we neglect flavor violating terms, therefore we take the Yukawa matrices to be diagonal. The $SU(2)_L \times U(1)_Y \rightarrow U(1)_{\text{em}}$ breaking Higgs VEV is chosen as

$$\langle H^T \rangle = (0 \ v), \quad v = \frac{\mu}{\sqrt{2\lambda}} = 174 \text{ GeV}, \quad (\text{A.7})$$

which gives mass terms for the electroweak gauge bosons and the fermions.

A.2 Lagrangian in the $SU(3)_c \times U(1)_{\text{em}}$ phase

Below the EWSB scale, the SM model has a residual $SU(3)_c \times U(1)_{\text{em}}$ gauge symmetry. Matter fermions fill vector-like representations of the gauge group, therefore it is convenient to use the Dirac fermions shown in table 4. The Lagrangian has two contributions

$$\mathcal{L}_{\text{EMSM}} = \mathcal{L}_{\text{YM}} + \mathcal{L}_{\text{fermions}}. \quad (\text{A.8})$$

The Yang-Mills term is analogous to the one in eq. (A.2), but this time with the photon field strength $F_{\mu\nu}$ in the electroweak sector. The fermion piece reads

$$\mathcal{L}_{\text{fermions}} = \sum_{i=1}^2 \bar{u}^i (i\not{D} - m_u^i) u^i + \sum_{i=1}^3 \bar{d}^i (i\not{D} - m_d^i) d^i + \sum_{i=1}^3 \bar{e}^i (i\not{D} - m_e^i) e^i, \quad (\text{A.9})$$

where we also include fermion masses. The fermion covariant derivative is defined in analogy to eq. (A.3), but with only strong and electromagnetic interactions.

A.3 Useful equations of motion

The only equations of motion needed to get rid of redundant operators are the ones for abelian gauge bosons. In the unbroken phase, the hypercharge field strength satisfies

$$\partial^\nu B_{\nu\mu} + g' J_\mu^{(Y)} = 0, \quad (\text{A.10})$$

where we define the current

$$J_\mu^{(Y)} = \sum_{i=1}^3 [y_q \bar{q}_L^i \gamma_\mu q_L^i + y_u \bar{u}_R^i \gamma_\mu u_R^i + y_d \bar{d}_R^i \gamma_\mu d_R^i + y_l \bar{l}_L^i \gamma_\mu l_L^i + y_e \bar{e}_R^i \gamma_\mu e_R^i] + y_H H^\dagger i \overleftrightarrow{D}_\mu H. \quad (\text{A.11})$$

Analogously, for the electromagnetic field strength in the broken phase

$$\partial^\nu F_{\nu\mu} + e J_\mu^{(\text{em})} = 0, \quad (\text{A.12})$$

where the electromagnetic current reads

$$J_\mu^{(\text{em})} = Q_u \sum_{i=1}^2 \bar{u}^i \gamma_\mu u^i + Q_d \sum_{i=1}^3 \bar{d}^i \gamma_\mu d^i + Q_e \sum_{i=1}^3 \bar{e}^i \gamma_\mu e^i. \quad (\text{A.13})$$

B Loops and RG equations

In this appendix we give results for one-loop diagrams, from which we derive the RG equations. We regularize UV divergences by computing loop integrals in $d = 4 - 2\epsilon$ dimensions, and subtract infinities using a mass-independent subtraction scheme. As done throughout the paper, we divide the discussion in two cases, correspondent to the two different EFTs.

B.1 RGE in the SM_χ EFT

Here we discuss the renormalization of the EFT described in section 2.1, with a specific focus on the dimension 6 operators listed in table 3. The wave-function renormalization factors,

generated by the one-loop diagrams in figures 2 and 3 have the following $1/\epsilon$ -pole structure

$$Z_{q_L^i} - 1 = -\frac{g_s^2}{16\pi^2\epsilon} \mathcal{C}_2(\mathbf{3}) - \frac{g^2}{16\pi^2\epsilon} \mathcal{C}_2(\mathbf{2}) - \frac{g'^2}{16\pi^2\epsilon} y_q^2 - \frac{\lambda_{u^{(i)}}^2 + \lambda_{d^{(i)}}^2}{32\pi^2\epsilon}, \quad (\text{B.1})$$

$$Z_{u_R^i} - 1 = -\frac{g_s^2}{16\pi^2\epsilon} \mathcal{C}_2(\mathbf{3}) - \frac{g'^2}{16\pi^2\epsilon} y_u^2 - \frac{\lambda_{u^{(i)}}^2}{16\pi^2\epsilon}, \quad (\text{B.2})$$

$$Z_{d_R^i} - 1 = -\frac{g_s^2}{16\pi^2\epsilon} \mathcal{C}_2(\mathbf{3}) - \frac{g'^2}{16\pi^2\epsilon} y_d^2 - \frac{\lambda_{d^{(i)}}^2}{16\pi^2\epsilon}, \quad (\text{B.3})$$

$$Z_{l_L^i} - 1 = -\frac{g^2}{16\pi^2\epsilon} \mathcal{C}_2(\mathbf{2}) - \frac{g'^2}{16\pi^2\epsilon} y_l^2 - \frac{\lambda_{l^i}^2}{32\pi^2\epsilon}, \quad (\text{B.4})$$

$$Z_{e_R^i} - 1 = -\frac{g'^2}{16\pi^2\epsilon} y_e^2 - \frac{\lambda_{l^{(i)}}^2}{16\pi^2\epsilon}, \quad (\text{B.5})$$

$$Z_H - 1 = \frac{g^2}{8\pi^2\epsilon} \mathcal{C}_2(\mathbf{2}) + \frac{g'^2}{8\pi^2\epsilon} y_H^2 - 3 \sum_i \frac{\lambda_{u^{(i)}}^2 + \lambda_{d^{(i)}}^2}{16\pi^2\epsilon} - \sum_i \frac{\lambda_{e^{(i)}}^2}{16\pi^2\epsilon}. \quad (\text{B.6})$$

Here $\mathcal{C}_2(N)$ denotes the Casimir for the $SU(N)$ fundamental representation, and the hypercharge values are assigned as follows

$$y_q = \frac{1}{6}, \quad y_u = \frac{2}{3}, \quad y_d = -\frac{1}{3}, \quad y_l = -\frac{1}{2}, \quad y_e = -1, \quad y_H = \frac{1}{2}. \quad (\text{B.7})$$

We have also define the Yukawa coupling vectors

$$\lambda_{u^{(i)}} = (\lambda_u, \lambda_c, \lambda_t), \quad \lambda_{d^{(i)}} = (\lambda_d, \lambda_s, \lambda_b), \quad \lambda_{e^{(i)}} = (\lambda_e, \lambda_\mu, \lambda_\tau). \quad (\text{B.8})$$

The Higgs quartic coupling does not induce any field renormalization. We now move to vertex corrections shown in figures 4 and 5. The sum of diagrams with gauge and Yukawa vertices gives the following one-loop corrections to the Wilson coefficients

$$\begin{aligned} \delta c_{\Gamma q}^{(i)} &= \frac{g_s^2}{16\pi^2\epsilon} \mathcal{C}_2(\mathbf{3}) c_{\Gamma q}^{(i)} + \frac{g^2}{16\pi^2\epsilon} \mathcal{C}_2(\mathbf{2}) c_{\Gamma q}^{(i)} + \frac{g'^2}{16\pi^2\epsilon} y_q^2 c_{\Gamma q}^{(i)} \\ &\quad + \frac{\lambda_{u^{(i)}}^2}{32\pi^2\epsilon} c_{\Gamma u}^{(i)} + \frac{\lambda_{d^{(i)}}^2}{32\pi^2\epsilon} c_{\Gamma d}^{(i)} - \frac{\lambda_{u^{(i)}}^2 + \lambda_{d^{(i)}}^2}{32\pi^2\epsilon} c_{\Gamma H}, \end{aligned} \quad (\text{B.9})$$

$$\delta c_{\Gamma u}^{(i)} = \frac{g_s^2}{16\pi^2\epsilon} \mathcal{C}_2(\mathbf{3}) c_{\Gamma u}^{(i)} + \frac{g'^2}{16\pi^2\epsilon} y_u^2 c_{\Gamma u}^{(i)} + \frac{\lambda_{u^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma q}^{(i)} - \frac{\lambda_{u^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma H}, \quad (\text{B.10})$$

$$\delta c_{\Gamma d}^{(i)} = \frac{g_s^2}{16\pi^2\epsilon} \mathcal{C}_2(\mathbf{3}) c_{\Gamma d}^{(i)} + \frac{g'^2}{16\pi^2\epsilon} y_d^2 c_{\Gamma d}^{(i)} + \frac{\lambda_{d^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma q}^{(i)} - \frac{\lambda_{d^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma H}, \quad (\text{B.11})$$

$$\delta c_{\Gamma l}^{(i)} = \frac{g^2}{16\pi^2\epsilon} \mathcal{C}_2(\mathbf{2}) c_{\Gamma l}^{(i)} + \frac{g'^2}{16\pi^2\epsilon} y_l^2 c_{\Gamma l}^{(i)} + \frac{\lambda_{l^{(i)}}^2}{32\pi^2\epsilon} c_{\Gamma e}^{(i)} - \frac{\lambda_{l^{(i)}}^2}{32\pi^2\epsilon} c_{\Gamma H}, \quad (\text{B.12})$$

$$\delta c_{\Gamma e}^{(i)} = \frac{g'^2}{16\pi^2\epsilon} y_e^2 c_{\Gamma e}^{(i)} + \frac{\lambda_{l^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma l}^{(i)} - \frac{\lambda_{l^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma H}, \quad (\text{B.13})$$

$$\begin{aligned} \delta c_{\Gamma H} &= -\frac{g^2}{8\pi^2\epsilon} \mathcal{C}_2(\mathbf{2}) c_{\Gamma H} - \frac{g'^2}{8\pi^2\epsilon} y_H^2 c_{\Gamma H} \\ &\quad - 3 \sum_i \frac{\lambda_{u^{(i)}}^2 - \lambda_{d^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma q}^{(i)} + 3 \sum_i \frac{\lambda_{u^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma u}^{(i)} - 3 \sum_i \frac{\lambda_{d^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma d}^{(i)} \\ &\quad + \sum_i \frac{\lambda_{l^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma l}^{(i)} - \sum_i \frac{\lambda_{l^{(i)}}^2}{16\pi^2\epsilon} c_{\Gamma e}^{(i)}. \end{aligned} \quad (\text{B.14})$$

The RG equations are derived by imposing that the bare Wilson coefficients are renormalization scale independent,

$$\frac{d}{d \ln \mu} \mathcal{C}_{\text{SM}_x} \Big|_{\text{ren}} = \gamma_{\text{SM}_x} \mathcal{C}_{\text{SM}_x} \Big|_{\text{ren}}, \quad (\text{B.19})$$

$$\gamma_{\text{SM}_x} \equiv -Z_{\text{SM}_x}^{-1} \frac{dZ_{\text{SM}_x}}{d \ln \mu} = -\frac{d}{d \ln \mu} (\delta Z_\lambda + \delta Z_Y). \quad (\text{B.20})$$

The last thing is to identify the μ dependence in the δZ_i matrices. The key point to observe here is that we work in a mass independent scheme, namely the matrices δZ_i do not have an explicit dependence on the mass scale but they only depend on μ through the Yukawa and gauge couplings. By defining at one loop

$$\delta Z_\lambda \equiv \frac{1}{\epsilon} \delta Z_\lambda^{(1)}(\lambda_i^2), \quad (\text{B.21})$$

$$\delta Z_Y \equiv \frac{1}{\epsilon} \delta Z_Y^{(1)}(g'^2), \quad (\text{B.22})$$

the anomalous dimension matrix reads

$$\gamma_{\text{SM}_x} \equiv \gamma_\lambda + \gamma_Y = \sum_i 2\lambda_i^2 \frac{\partial \delta Z_\lambda^{(1)}(\lambda_i^2)}{\partial \lambda_i^2} + 2g'^2 \frac{\partial \delta Z_Y^{(1)}(g'^2)}{\partial g'^2}. \quad (\text{B.23})$$

B.2 RGE in the EMSM_χ EFT

Below the EWSB scale wave-function renormalization is only due to gauge interactions. The results can be derived from eqs. (B.1)–(B.5) for fermions above the EWSB scale, with identical QCD contribution and electromagnetic factor obtained by replacing the hypercharges with the electric charges

$$Q_u = \frac{2}{3}, \quad Q_d = -\frac{1}{3}, \quad Q_e = -1. \quad (\text{B.24})$$

They all cancel again with the associated vertex corrections, therefore we do not need to further consider them.

As discussed in the paper there are two classes of vertex corrections also in this case. The first corrections are due to the SM four-fermion interactions, as shown in figure 7. These diagrams do not vanish only if we start from an interaction between the DM bilinear and the *axial* current of SM fermions. The explicit shifts read

$$\delta c_{\Gamma V u}^{(i)} = -\frac{G_F g_{V u}}{\sqrt{2} \pi^2 \epsilon} L_m, \quad (\text{B.25})$$

$$\delta c_{\Gamma V d}^{(i)} = -\frac{G_F g_{V d}}{\sqrt{2} \pi^2 \epsilon} L_m, \quad (\text{B.26})$$

$$\delta c_{\Gamma V e}^{(i)} = -\frac{G_F g_{V e}}{\sqrt{2} \pi^2 \epsilon} L_m, \quad (\text{B.27})$$

$$\delta c_{\Gamma A u}^{(i)} = -\frac{G_F g_{A u}}{\sqrt{2} \pi^2 \epsilon} L_m, \quad (\text{B.28})$$

$$\delta c_{\Gamma A d}^{(i)} = -\frac{G_F g_{A d}}{\sqrt{2} \pi^2 \epsilon} L_m, \quad (\text{B.29})$$

$$\delta c_{\Gamma A e}^{(i)} = -\frac{G_F g_{A e}}{\sqrt{2} \pi^2 \epsilon} L_m, \quad (\text{B.30})$$

and

$$\delta Z_{\text{em}} = -\frac{4}{3} \frac{e^2}{16\pi^2 \epsilon} \begin{pmatrix} 3Q_u^2 & 3Q_u Q_d & 3Q_u^2 & 3Q_u Q_d & 3Q_u Q_d & Q_u Q_e & Q_u Q_e & Q_u Q_e & 0 & 0 & 0 & 0 & 0 & 0 \\ 3Q_d Q_u & 3Q_d^2 & 3Q_d Q_u & 3Q_d^2 & 3Q_d^2 & Q_d Q_e & Q_d Q_e & Q_d Q_e & 0 & 0 & 0 & 0 & 0 & 0 \\ 3Q_u^2 & 3Q_u Q_d & 3Q_u^2 & 3Q_u Q_d & 3Q_u Q_d & Q_u Q_e & Q_u Q_e & Q_u Q_e & 0 & 0 & 0 & 0 & 0 & 0 \\ 3Q_d Q_u & 3Q_d^2 & 3Q_d Q_u & 3Q_d^2 & 3Q_d^2 & Q_d Q_e & Q_d Q_e & Q_d Q_e & 0 & 0 & 0 & 0 & 0 & 0 \\ 3Q_d Q_u & 3Q_d^2 & 3Q_d Q_u & 3Q_d^2 & 3Q_d^2 & Q_d Q_e & Q_d Q_e & Q_d Q_e & 0 & 0 & 0 & 0 & 0 & 0 \\ \hline 3Q_e Q_u & 3Q_e Q_d & 3Q_e Q_u & 3Q_e Q_d & 3Q_e Q_d & Q_e^2 & Q_e^2 & Q_e^2 & 0 & 0 & 0 & 0 & 0 & 0 \\ 3Q_e Q_u & 3Q_e Q_d & 3Q_e Q_u & 3Q_e Q_d & 3Q_e Q_d & Q_e^2 & Q_e^2 & Q_e^2 & 0 & 0 & 0 & 0 & 0 & 0 \\ 3Q_e Q_u & 3Q_e Q_d & 3Q_e Q_u & 3Q_e Q_d & 3Q_e Q_d & Q_e^2 & Q_e^2 & Q_e^2 & 0 & 0 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \quad (\text{B.35})$$

The RG equations read

$$\frac{d}{d \ln \mu} \mathcal{C}_{\text{EMSM}_\chi} \Big|_{\text{ren}} = \gamma_{\text{EMSM}_\chi} \mathcal{C}_{\text{EMSM}_\chi} \Big|_{\text{ren}}, \quad (\text{B.36})$$

$$\gamma_{\text{EMSM}_\chi} \equiv -Z_{\text{EMSM}_\chi}^{-1} \frac{dZ_{\text{EMSM}_\chi}}{d \ln \mu} = -\frac{d}{d \ln \mu} (\delta Z_m + \delta Z_{\text{em}}), \quad (\text{B.37})$$

where the anomalous dimension can be computed analogously to what done in eq. (B.23).

C Full solution of the RG system

The evolution operator U_Λ appearing in eq. (4.5) connects the mediator with the nuclear scale. In this appendix we derive an expression for this operator. As described extensively in the paper, this connection requires three different steps, encoded in three different contributions

$$U_\Lambda = U_{\text{EMSM}_\chi} U_{\text{match}} U_{\text{SM}_\chi}(t_\Lambda). \quad (\text{C.1})$$

The matrix $U_{\text{SM}_\chi}(t_\Lambda)$ evolves the Wilson coefficients from Λ down to m_Z , whereas the matrix U_{EMSM_χ} describes the evolution from m_Z to $\mu \sim 1\text{--}2 \text{ GeV}$. The intermediate matching at the EWSB scale is taken care of by the matrix U_{match} .

We start by setting up a general method to solve the RG system, which can be applied both above and below the EWSB scale. In both cases we always have to deal with a system

$$\frac{dc(t)}{dt} = \gamma(t)c(t). \quad (\text{C.2})$$

The only scale dependence in $\gamma(t)$ comes from SM running couplings, namely

$$\gamma(t) = \sum_j \frac{g_j^2(t)}{16\pi^2} \gamma_j. \quad (\text{C.3})$$

Here, the index j runs over all SM running couplings $g_j(t)$, whereas the matrices γ_j are constant. The running of the SM couplings can be found by solving the RG equations given in refs. [108–110]. In both EFTs $t = 0$ is one boundary of our integration range, thus we rewrite the SM running couplings as follows

$$g_j^2(t) = g_j^2(0) + \Delta g_j^2(t), \quad (\text{C.4})$$

where $t = 0$ at the Z pole. The SM couplings at the Z pole can be found in refs. [96, 97]. The anomalous dimension matrix has then the form

$$\gamma(t) = \sum_j \frac{g_j^2(0)}{16\pi^2} \gamma_j + \sum_j \frac{\Delta g_j^2(t)}{16\pi^2} \gamma_j \equiv \gamma_0 + \gamma_1(t). \quad (\text{C.5})$$

This setup is identical to a time-dependent perturbation theory problem in quantum mechanics with time replaced by the dimensionless variable $t = \ln(\mu/m_Z)$. In particular, the matrix $\gamma_1(t)$ can be treated as a time-dependent perturbation to the constant matrix γ_0 , since their difference is at most a logarithmic running over two or three orders of magnitude. The procedure to set up a perturbative series is well known. We first define the “interaction picture” variables

$$c_I(t) = \exp[-\gamma_0 t] c(t), \quad (\text{C.6})$$

$$\gamma_{1I}(t) = \exp[-\gamma_0 t] \gamma_1 \exp[\gamma_0 t]. \quad (\text{C.7})$$

The Wilson coefficient vector satisfies a Schwinger-Tomonaga equation

$$\frac{dc_I(t)}{dt} = \gamma_{1I}(t) c_I(t), \quad (\text{C.8})$$

whose formal solution is the Dyson series

$$c_I(t) = \mathcal{T} \exp \left(\int_0^t dt' \gamma_{1I}(t') \right) c_I(0), \quad (\text{C.9})$$

$$\mathcal{T} \exp \left(\int_0^t dt' \gamma_{1I}(t') \right) = 1 + \int_0^t dt'_1 \gamma_{1I}(t'_1) + \int_0^t dt'_1 \int_0^{t'_1} dt'_2 \gamma_{1I}(t'_1) \gamma_{1I}(t'_2) + \dots \quad (\text{C.10})$$

We apply this result to derive the full evolution operator as defined in eq. (C.1). The running from the mediator to the EWSB scale is obtained by applying the linear operator

$$U_{\text{SM}_\chi}(t_\Lambda) = \left[\mathcal{T} \exp \left(- \int_0^{t_\Lambda} dt \gamma_{\text{SM}_\chi 1I}(t) \right) \right] \exp[-\gamma_{\text{SM}_\chi 0} t_\Lambda]. \quad (\text{C.11})$$

The analogous evolution from the EWSB scale down to the nuclear scale is described by

$$U_{\text{EMSM}_\chi} = \exp[\gamma_{\text{EMSM}_\chi 0} t_N] \left[\mathcal{T} \exp \left(\int_0^{t_N} dt \gamma_{\text{EMSM}_\chi 1I}(t) \right) \right]. \quad (\text{C.12})$$

Finally, the matching at the intermediate scale is achieved by using

$$U_{\text{match}} = \frac{1}{2} \left(\begin{array}{ccc|ccc|ccc|c}
 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2g_{Vu} \\
 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2g_{Vd} \\
 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 2g_{Vu} \\
 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 2g_{Vd} \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 & 2g_{Vd} \\
 \hline
 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 2g_{Ve} \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 2g_{Ve} \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 2g_{Ve} \\
 \hline
 -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2g_{Au} \\
 -1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2g_{Ad} \\
 0 & 0 & 0 & 0 & 0 & -1 & 1 & 0 & 0 & 0 & 2g_{Au} \\
 0 & 0 & 0 & 0 & 0 & -1 & 0 & 1 & 0 & 0 & 2g_{Ad} \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 1 & 2g_{Ad} \\
 \hline
 0 & 0 & 0 & -1 & 1 & 0 & 0 & 0 & 0 & 0 & 2g_{Ae} \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 & 2g_{Ae} \\
 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 & 2g_{Ae}
 \end{array} \right). \tag{C.13}$$

D A simple recipe for an approximate analytical solution

In this appendix we describe a simple analytical way to perform the RG evolution and compute direct detection cross sections based on our results. This is meant to be a useful recipe for practitioners. What is given here is the 0-th order of the Dyson series in eq. (C.9), which neglects the running of the SM couplings. This approximation is quite satisfactory for our purposes since it induces errors at the level of 10% in the scale Λ if the DM couples to the top quark, and at the level of 1% without this coupling.

Let us consider the situation where, starting from a UV complete model of singlet fermion WIMP, integrating out the mediators at the scale Λ generates a subset of the dimension 6 operators in table 6. Then the spin-independent rate for the scattering off a target nucleus with Z protons and A neutrons is obtained through the following straightforward steps.

- (i) Write down the Wilson coefficients at the scale Λ organized as in eq. (2.9), and define

$$c_\Lambda \equiv \mathcal{C}_{\text{SM}_\chi}(t_\Lambda), \tag{D.1}$$

where $t_\Lambda \equiv \ln(\Lambda/m_Z)$;

- (ii) Evolve the vector of Wilson coefficients c_Λ down to the nuclear scale using

$$c_N \equiv U_{\text{EMSM}_\chi} U_{\text{match}} \exp[-\gamma_{\text{SM}_\chi 0} t_\Lambda] c_\Lambda, \tag{D.2}$$

(iii) After obtaining c_N , its first two components

$$(c_N)_1 \equiv c_{VVu}^{(1)}, \quad (c_N)_2 \equiv c_{VVd}^{(1)} \quad (\text{D.6})$$

directly appear in the spin-independent WIMP-nucleus cross section which can be computed according to

$$\sigma_{\mathcal{N}}^{\text{SI}} = \frac{m_\chi^2 m_{\mathcal{N}}^2}{(m_\chi + m_{\mathcal{N}})^2 \pi \Lambda^4} |c_{VVu}^{(1)}(A + Z) + c_{VVd}^{(1)}(2A - Z)|^2, \quad (\text{D.7})$$

where $m_{\mathcal{N}}$ is the mass of the target nucleus.
