Background

Emphysematous cholecystitis (EC) is an entity with high morbidity and mortality, and therefore require a diagnosis agile and dynamic, allowing appropriate management to avoid complications. The emergency ultrasound (US) allows a versatile and comprehensive management, improving the prognosis of this disease in the majority of cases.

Objective

we present a case of EC, diagnosed at ER, through the use of US scanning used by Emergency Phisicians.

Patients and methods

a patient with abdominal pain, with a final diagnosis of an EC assessing US, performed by EP.

Results

We report the case of a 72 year old patient with prior stroke without sequelae and hypertensive, with abdominal pain of 7 days duration, high fever and bilious vomiting. Physical examination was marked hypotension (80/45 mmHg), distal coldness, pallor and sweating, 38.5 ° C, 145 spm. The distended abdomen with abolished peristalsis and positive Murphy right upper quadrant. Rest without findings of interest. Analytically glucose was 505 mg / dl, creatinine of 2.44 mg / dl, bilirubin 2.2 mg / dl, AST 350, LDH 407, amylase 125, 19500 leukos with neutrophilia and pH of 7.13, with lactic 12. Was performed in consultation abdominal US showed a thickened gallbladder wall (8 mm), wellcircumscribed, oval, distended and gas in the same light, compatible with emphysematous cholecystitis. Support measures were initiated, antibiotics, insulin therapy and emergency surgery was indicated. This allowed a favorable high after joining UCI in 7 days without further complications.

Conclusion

EC is a rare entity that represents 1% of all cholecystitis, clinically indistinguishable, but with a worse prognosis (25% mortality) and more complications. Here debut comes as poorly controlled diabetes. The use of abdominal US in ER allows for both a rapid and versatile, with proper treatment start, this being vital to good patient outcomes.
