ABSTRACT

The purpose of this survey is to classify systematically a widely ranging list of characterizations of nonsingular M-matrices from the economics and mathematics literatures. These characterizations are grouped together in terms of their relations to the properties of (1) positivity of principal minors, (2) inverse-positivity and splittings, (3) stability and (4) semipositivity and diagonal dominance. A list of forty equivalent conditions is given for a square matrix $A$ with nonpositive off-diagonal entries to be a nonsingular M-matrix. These conditions are grouped into classes in order to identify those that are equivalent for arbitrary real matrices $A$. In addition, other remarks relating nonsingular M-matrices to certain complex matrices are made, and the recent literature on these general topics is surveyed.

I. INTRODUCTION

Very often problems in the biological, physical and social sciences can be reduced to problems involving matrices which, due to certain constraints, have some special structure. One of the most common situations is where the finite square matrix $A$ in question has nonpositive off-diagonal and nonnegative diagonal entries, that is, $A$ is of the type:

$$
A = \begin{bmatrix}
  a_{11} & -a_{12} & -a_{13} & \cdots \\
  -a_{21} & a_{22} & -a_{23} & \cdots \\
  -a_{31} & -a_{32} & a_{33} & \cdots \\
  \vdots & \vdots & \vdots & \ddots
\end{bmatrix}
$$
where the \( a_{ij} \) are nonnegative. Such matrices usually occur in relation to systems of linear or nonlinear equations or eigenvalue problems in a wide variety of areas, including finite-difference or finite-element methods for partial differential equations, input-output production and growth models in economics, linear complementarity problems in operations research and Markov processes in probability and statistics.

We adopt the traditional notation here (of Fiedler and Ptak [10]) by letting \( Z^{n,n} \) denote the set of all \( n \times n \) real matrices \( A = (a_{ij}) \) with \( a_{ij} < 0 \) for all \( i \neq j, \ 1 \leq i, j \leq n \).

Our purpose is to give a systematic treatment of the characterizations of a subset of matrices in \( Z^{n,n} \) first studied systematically by Ostrowski [24].

**Definition.** An \( n \times n \) matrix \( A \) that can be expressed in the form \( A = sI - B \), where \( B = (b_{ij}) \) with \( b_{ii} > 0, \ 1 < i, j < n \), and \( s > \rho(B) \), the maximum of the moduli of the eigenvalues of \( B \), is called an \( M \)-matrix.

We shall be primarily concerned in this survey with nonsingular \( M \)-matrices, and it is easy to see that this is the class of those \( A \) given in the Definition for which \( s > \rho(B) \), from the Perron-Frobenius theory.

It should be mentioned that the theory of nonnegative matrices developed by Perron [26,27] and Frobenius [11-13] provided a certain essential background for Ostrowski's work and the work of others on \( M \) matrices. For example, it is easy to see from the Perron-Frobenius theory of nonnegative matrices that if \( A \) is a nonsingular \( M \)-matrix, then the diagonal elements \( a_{ii} \) of \( A \) must be positive. Also, \( A \) can be represented as \( A = sI - B, B \geq 0 \), in many different ways, but in each case it follows that \( s > \rho(B) \). In particular, then, the class of nonsingular \( M \)-matrices forms a proper subclass of \( M \)-matrices which forms a proper subclass of matrices in \( Z^{n,n} \).

No attempt will be made here to systematically trace the history of the development of the theory of \( M \)-matrices. It appears, however, that the term \( M \)-matrix was first used by Ostrowski [24,25] in reference to the work of Minkowski [20,21], who proved that if \( A \in Z^{n,n} \) has all of its row sums positive, then the determinant of \( A \) is positive. Papers following the early work of Ostrowski have primarily been produced by two groups of researchers, one in mathematics, the other in economics.

The mathematicians have mainly had in mind the applications of \( M \)-matrices to the establishment of bounds on eigenvalues and on the establishment of convergence criteria for iterative methods for the solution of large sparse systems of linear equations. Meanwhile, the economists have studied \( M \)-matrices in connection with gross substitutability, stability of a general equilibrium and Leontief’s input-output analysis in economic systems [18]. With this in mind, it should be mentioned that the terms productive matrix, Leontief matrix and Minkowski matrix have all been used in the economics
literature to describe what we call a nonsingular $M$-matrix. Some of the contributions of individual researchers in these areas will be mentioned later in the paper.

Because the concept of an $M$-matrix has been applied to such diverse areas of the sciences, much of the theory has been developed at least partially in isolation. As a result, much of the terminology and notation have been different, and there is often formal overlap in the literature (this is pointed out quite vividly by Varga [39]). One of the purposes of this survey is to collect the various characterizations of nonsingular $M$-matrices that have been developed and applied by various researchers into a list that might make it possible for the reader to get an overall picture of the theory. The first systematic effort to characterize $M$-matrices was by Fiedler and Ptak [10]. An initial survey of the theory of $M$-matrices was made by Poole and Boullion [28]. Varga [39] has surveyed the role of diagonal dominance in the theory of $M$-matrices. In addition, Schröder [33] has surveyed some of the properties of nonsingular $M$-matrices, using operator theory and partially ordered linear spaces. Meanwhile, Kaneko [17] has compiled a list of characterizations and applications of nonsingular $M$-matrices in terms of linear complementarity problems in operations research. However, our objectives and our approach are quite different in this survey.

Section II is devoted to characterizing in a systematic way those matrices in $\mathbb{Z}^{n,n}$ that are nonsingular $M$-matrices. Characterizations of certain real and complex matrices related to $M$ matrices are also given, and an attempt is made to indicate where in the literature these characterizations may be found.

No proofs are given in this survey. The proofs of the various results can be found in the original papers.

The following notation will be used.

- $\emptyset$: The empty set.
- $0$: A vector or matrix of all zeros.
- $I$: An identity matrix.
- $S$: A signature matrix, that is, a diagonal matrix with diagonal entries $+1$ or $-1$.
- $\mathbb{C}$: The set of complex numbers.
- $\mathbb{R}$: The set of real numbers.
- $\mathbb{C}^n$: The vector space of $n$-vectors over $\mathbb{C}$.
- $\mathbb{R}^n$: The vector space of $n$-vectors over $\mathbb{R}$.
- $\mathbb{R}_+$: The nonnegative orthant, that is, vectors in $\mathbb{R}^n_+$ having all nonnegative components. If $x \in \mathbb{R}^n_+$ we write $x \geq 0$ if $x \neq 0$, and $x \geq 0$ if $x > 0$ or $x = 0$. If $x$ has all positive components we write $x > 0$.
- $\mathbb{C}^{n,n}$: The set of all $n \times n$ matrices over $\mathbb{C}$.
- $\mathbb{R}^{n,n}$: The set of all $n \times n$ matrices over $\mathbb{R}$.
- $\mathbb{Z}^{n,n}$: The set of all $A \in \mathbb{Z}^{n,n}$ with $a_{ij} < 0$ if $i \neq j$, $1 \leq i, j \leq n$. 

Let $A \in \mathbb{R}^{n,n}$.

$A > 0$ Indicates that each entry of $A$ is nonnegative and that $A \neq 0$.

$A \geq 0$ Indicates that $A > 0$ or $A = 0$.

$A^t$ The transpose of $A$.

$A^{-1}$ The inverse of $A$.

$\rho(A)$ The spectral radius of $A$; here $\rho(A) = \max\{|\lambda| : \det(\lambda I - A) = 0\}$.

II. CHARACTERIZATIONS

For practical purposes in characterizing nonsingular $M$-matrices, it is evident that we can often begin by assuming that $A \in \mathbb{R}^{n,n}$. However, many of the statements of these characterizations are equivalent without this assumption. We have attempted here to group together all such statements into certain categories. Moreover, certain other implications follow without assuming that $A \in \mathbb{R}^{n,n}$, and we point out such implications in the following inclusive theorem. All matrices and vectors considered in this theorem are real.

**Theorem 1.** Let $A \in \mathbb{R}^{n,n}$. Then for each fixed letter $\mathcal{C}$ representing one of the conditions below, conditions $\mathcal{C}_i$ are equivalent for each $i$. Moreover letting $\mathcal{C}$ then represent any of the equivalent conditions $\mathcal{C}_i$, the following implications hold:

Finally, if $A \in \mathbb{R}^{n,n}$, then each of the following forty conditions is equivalent to the statement: $A$ is a nonsingular $M$-matrix.
Positivity of Principal Minors

A₁. All the principal minors of A are positive. That is, the determinant of each submatrix of A obtained by deleting a set, possibly empty, of corresponding rows and columns of A is positive.

A₂. Every real eigenvalue of each principal submatrix of A is positive.

A₃. A + D is nonsingular for each nonnegative diagonal matrix D.

A₄. For each \( x \neq 0 \) there exists a positive diagonal matrix D such that

\[ x^t ADx > 0. \]

A₅. For each \( x \neq 0 \) there exists a nonnegative diagonal matrix D such that

\[ x^t ADx > 0. \]

A₆. A does not reverse the sign of any vector. That is, if \( x \neq 0 \), then for some subscript \( i \),

\[ x_i (Ax)_i > 0. \]

A₇. For each signature matrix S there exists an \( x > 0 \) such that

\[ SASx > 0. \]

B₈. The sum of all the \( k \times k \) principal minors of A is positive for \( k = 1, 2, \ldots, n \).

C₉. Every real eigenvalue of A is positive.

C₁₀. A + \( \alpha I \) is nonsingular for each scalar \( \alpha > 0 \).

D₁₁. All the leading principal minors of A are positive.

D₁₂. There exist lower and upper triangular matrices L and U respectively, with positive diagonals, such that

\[ A = LU. \]

E₁₃. There exists a strictly increasing sequence of subsets \( \emptyset \neq S_1 \subset \cdots \subset S_n = \{1, \ldots, n\} \) such that the determinant of the principal submatrix of A formed by choosing row and columns indices from \( S_i \) is positive for \( i = 1, \ldots, n \).

E₁₄. There exists a permutation matrix \( P \) and lower and upper triangular matrices L and U respectively, with positive diagonals, such that

\[ PAP^t = LU. \]
Inverse-Positivity and Splittings

F₁₅. A is inverse-positive. That is, $A^{-1}$ exists and

$$A^{-1} \succ 0.$$  

F₁₆. A is monotone. That is,

$$Ax \geq 0 \Rightarrow x \geq 0 \quad \text{for all} \quad x \in \mathbb{R}^n.$$  

F₁₇. A has a convergent regular splitting. That is, A has a representation

$$A = M - N, \quad M^{-1} \succ 0, \quad N \succeq 0$$  

with $M^{-1}N$ convergent. That is, $\rho(M^{-1}N) < 1$.

F₁₈. A has a convergent weak regular splitting. That is, A has a representation

$$A = M - N, \quad M^{-1} \succ 0, \quad M^{-1}N \succeq 0$$  

with $M^{-1}N$ convergent.

F₁₉. A has a weak regular splitting, and there exists $x > 0$ with $Ax > 0$.

F₂₀. There exist inverse-positive matrices $M₁$ and $M₂$ with

$$M₁ \leq A \leq M₂.$$  

F₂₁. There exist an inverse-positive matrix $M$, with $M \succeq A$, and a nonsingular $M$-matrix $B$ such that $A = MB$.

F₂₂. There exist an inverse-positive matrix $M$ and a nonsingular $M$-matrix $B$ such that $A = MB$.

G₂₃. Every weak regular splitting of A is convergent.

H₂₄. Every regular splitting of A is convergent.

Stability

I₂₅. There exists a positive diagonal matrix $D$ such that

$$AD + DA^t$$  

is positive definite.

I₂₆. A is diagonally similar to a matrix whose symmetric part is positive definite. That is, there exists a positive diagonal matrix $E$ such that for
B = E^{-1}AE, the matrix

\[
(B + B')/2
\]

is positive definite.

I_{26}. For each nonzero positive semidefinite matrix P, the matrix PA has a positive diagonal element.

I_{27}. Every principal submatrix of A satisfies condition I_{25}.

J_{28}. A is positive stable. That is, the real part of each eigenvalue of A is positive.

J_{29}. There exists a symmetric positive definite matrix W such that

\[
AW + WA^T
\]

is positive definite.

J_{30}. A + I is nonsingular, and

\[
G = (A + I)^{-1}(A - I)
\]

is convergent.

J_{31}. A + I is nonsingular, and for

\[
G = (A + I)^{-1}(A - I),
\]

there exists a positive definite symmetric matrix W such that

\[
W - G^T WG
\]

is positive definite.

Semipositivity and Diagonal Dominance

K_{32}. A is semipositive. That is, there exists x > 0 with Ax > 0.

K_{33}. There exists x \geq 0 with Ax > 0.

K_{34}. There exists x > 0 with Ax = 0.

K_{35}. There exists a positive diagonal matrix D such that AD has all positive row sums.

L_{36}. There exists x > 0 with Ax \geq 0 such that if (Ax)_{i_0} = 0, then there exist indices 1 \leq i_1, \ldots, i_r \leq n with a_{i_ki_{k+1}} \neq 0 for 0 \leq k < r - 1 and (Ax)_{i_r} > 0.

M_{37}. There exists x > 0 with Ax > 0 and

\[
\sum_{i=1}^{i} a_{ii}x_i > 0
\]

for each i = 1, 2, \ldots, n.
N\textsubscript{38}. There exists $x > 0$ such that for each signature matrix $S$,

\[ SASx > 0. \]

N\textsubscript{39}. $A$ has all positive diagonal elements, and there exists a positive diagonal matrix $D$ such that $AD$ is strictly diagonally dominant. That is,

\[ a_{ii}d_i > \sum_{j \neq i} |a_{ij}|d_j \]

for $i = 1, 2, \ldots, n$.

N\textsubscript{40}. $A$ has all positive diagonal elements, and there exists a positive diagonal matrix $D$ such that $D^{-1}AD$ is strictly diagonally dominant.

We remark again that Theorem 1 identifies those conditions characterizing nonsingular $M$-matrices that are equivalent for an arbitrary matrix in $\mathbb{R}^{n \times n}$, as well as certain implications that hold for various classes of conditions. For example, $A_1$ through $A_7$ are equivalent, and $A \Rightarrow B$ for an arbitrary matrix in $\mathbb{R}^{n \times n}$. We remark also that it follows from the work of Ostrowski [24] and Varga [38] that a matrix $A \in \mathbb{Z}^{n \times n}$ is a nonsingular $M$-matrix if and only if each irreducible submatrix, not necessarily proper, of $A$ is a nonsingular $M$-matrix and thus satisfies one of the equivalent conditions in Theorem 1. It should also be pointed out that some of the classes have left-right duals with $A$ replaced by $A^t$.

The problem of giving proper credit to those originally responsible for the various characterizations listed in Theorem 1 is difficult, if not impossible. The situation is complicated by the fact that many of the characterizations are implicit in the work of Perron [26, 27] and Frobenius [11–13] and in the work of Ostrowski [24, 25], but were not given there in their present form. Another complicating factor is that the diversification of the applications of $M$-matrices has led to certain conditions being derived independently. We attempt in this survey only to give references to the literature where the various proofs can be found.

First of all condition $A_1$, which is known as the Hawkins-Simon [15] condition in the economics literature, was taken by Ostrowski [24] as the definition for $A \in \mathbb{Z}^{n \times n}$ to be a nonsingular $M$-matrix. He then proceeded to show the equivalence of his definition with ours; namely, that $A$ has a representation $A = sI - B$ with $B \geq 0$ and $s > \rho(B)$. Condition $A_2$ is also in [24]. Condition $A_3$ was shown to be equivalent to $A_1$ by Willson [40], while conditions $A_4$, $A_5$ and $A_6$ were listed by Fiedler and Ptak [10]. Condition $A_6$ is also given by Gale and Nikaido [14], and $A_7$ was shown to be equivalent to $A_1$ by Moylan [22].
Condition B₉ can be found in Johnson [16], and C₉, C₁₀, D₁₁, D₁₂, E₁₃ and E₁₄ are in Fiedler and Ptak [10].

Condition F₁₅ is in the original paper by Ostrowski [24], condition F₁₆ was shown to be equivalent to F₁₅ by Collatz [7], condition F₁₇ is implicit in the work of Varga [38] on regular splittings, condition F₁₈ is in the work of Schneider, [32] and F₁₉ and F₂₀ are in the work of Price [29]. Conditions F₂₁, F₂₂ and G₂₃ are in Ortega and Rheinboldt [42] and H₂₄ is given by Varga [38].

Condition I₂₅ is in the work of Tartar [35] and of Araki [2]. The equivalence of I₂₆, I₂₇ and I₂₈ to I₂₅ is shown by Barker, Berman and Plemmons [3]. The stability condition J₃₀ is in the work of Ostrowski [24]; its equivalence with J₃₁ is the Lyapunov [19] theorem. The equivalence of J₃₁ with J₃₂ is given by Taussky [36], and the equivalence of J₃₂ with J₃₁ is the Stein [34] theorem.

Conditions K₃₃, K₃₄ and K₃₅ are given by Schneider [30] and Fan [9]. Condition L₃₆ is given in a slightly weaker form by Bramble and Hubbard [5]; in our form, by Varga [39]. Condition M₃₇ is in the work of Beauwens [4], and N₃₈ is in that of Moylan [22]. Conditions N₃₉ and N₄₀ are essentially given by Fiedler and Ptak [10].

Now let C represent any of the equivalent conditions Cᵢ, and let A ∈ ℝⁿⁿ. That N⇒I was established in Barker, Berman and Plemmons [3]. That I⇒J is shown by Lyapunov [19], and that I⇒A is also shown by Barker, Berman and Plemmons [3]. The implications A⇒B⇒C, A⇒D⇒E and J⇒C are immediate. That A⇒K can be found in Nikaido [23], and the implication K⇒L is immediate. That F⇒K can be found in Schneider [30]. Finally, the implication F⇒G is given by Varga [38], and the implication G⇒H is immediate.

It is not known by the author whether M⇒L.

Next, we consider necessary and sufficient conditions for an arbitrary matrix A ∈ ℝⁿⁿ to be a nonsingular M-matrix. In the following theorem, we do not assume that A has nonpositive off-diagonal entries.

**Theorem 2.** Let A ∈ ℝⁿⁿ, n > 2. Then each of the following conditions is equivalent to the statement: A is a nonsingular M-matrix.

1. A + D is inverse-positive for each nonnegative diagonal matrix D.
2. A + αI is inverse-positive for each scalar α > 0.
3. Each principal submatrix of A is inverse-positive.
4. Each principal submatrix of A of orders 1, 2 and n is inverse-positive.

In view of condition F₁₅ in Theorem 1, the proof of Theorem 2 reduces to that of showing that any A ∈ ℝⁿⁿ satisfying one of these conditions can have no positive off-diagonal elements. That this is true if condition 1 or 2
holds is shown by Willson [40], and that it is true if condition 3 or 4 holds is shown by Cottle and Veinott [8].

We now relate some of the characterizations of nonsingular M-matrices to matrices over the complex field.

For $A \in \mathbb{C}^{n \times n}$ we define its comparison matrix $\mathcal{M}(A) = (m_{ij}) \in \mathbb{R}^{n \times n}$ given by

$$m_{ii} = |a_{ii}|, \quad m_{ij} = -|a_{ij}|, \quad i \neq j, \quad 1 \leq i, j \leq n$$

and we define

$$\Omega(A) = \{ B = (b_{ij}) \in \mathbb{C}^{n \times n} : |b_{ij}| = |a_{ij}|, \quad 1 \leq i, j \leq n \}$$

to be the set of equimodular matrices associated with $A$.

Our objective is to characterize matrices $A$ for which $\mathcal{M}(A)$ is a nonsingular M-matrix. Such matrices will be called H-matrices after Ostrowski [24]. We first use Theorem 1 to characterize certain real H-matrices.

**Theorem 3.** Let $A \in \mathbb{R}^{n \times n}$ have all positive diagonal elements. Then $A$ is a matrix if and only if $A$ satisfies one of the equivalent conditions $N_{35}$, $N_{39}$ or $N_{40}$ of Theorem 1.

That $N_{38}$ is equivalent to $\mathcal{M}(A)$ being a nonsingular M-matrix is shown by Moylan [22], while $N_{39}$ and $N_{40}$ are given by Schneider [30].

In order to characterize complex H-matrices, we introduce the following splittings of $A \in \mathbb{C}^{n \times n}$. Suppose the diagonals of $A$ are all nonzero, and let

$$A = M - N = D - L - U,$$

where $D = \text{diag}(a_{11}, \ldots, a_{nn})$ and where $-L$ and $-U$ are respectively the lower and upper parts of $A$. Different choices of $M$ in this splitting lead to certain well known iteration matrices $T = M^{-1}N$. For $\omega > 0$ we define

$$J_\omega(A) = \omega D^{-1} (L + U) + (1 - \omega) I,$$

$$\mathcal{L}_\omega(A) = (D - \omega L)^{-1} [(1 - \omega) D + \omega U],$$

$$S_\omega(A) = (D - \omega U)^{-1} [(1 - \omega) D + \omega L] (D - \omega L)^{-1} [(1 - \omega) D + \omega U],$$

respectively the (point) Jacobi overrelaxation iteration matrix, the successive
overrelaxation iteration matrix and the symmetric successive overrelaxation
iteration matrix associated with $A$. These matrices form the iteration
matrices for the widely used JOR, SOR and SSOR iteration procedures for
solving systems of linear equations. We are interested in conditions under
which these iteration matrices are convergent. It turns out that the theory of
$M$-matrices plays a fundamental role in such investigations.

Our final characterization theorem is for nonsingular $H$-matrices in $\mathbb{C}^{n \times n}$.

**Theorem 4.** Let $A \in \mathbb{C}^{n \times n}$ have all nonzero diagonal elements. Then
each of the following conditions is equivalent to the statement: $A$ is a
nonsingular $H$-matrix.

1. For each $B \in \mathbb{C}^{n \times n}$, $\Re(B) \supseteq \Re(A)$ implies $B$ is nonsingular.
2. For each $B \in \Omega(A)$,

$$0 < \omega < \frac{2}{1 + \rho(J_1(B))}$$

implies that

$$\rho(J_\omega(B)) < 1.$$

3. For each $B \in \Omega(A)$,

$$0 < \omega < \frac{2}{1 + \rho(|J_1(B)|)}$$

implies that

$$\rho(C_\omega(B)) < 1.$$

4. For each $B \in \Omega(A)$,

$$0 < \omega < \frac{2}{1 + \rho(|J_1(B)|)}$$

implies that

$$\rho(S_\omega(B)) < 1.$$
Conditions 2 and 3 in Theorem 4 are in the work of Varga [39] in relation to characterizations of diagonal dominance, and condition 4 is in the work of Alefeld and Varga [1]. Finally, condition 1 is given by Ostrowski [25]. A related result is given by Camion and Hoffman [1966], who used the theory of the alternative to show that for each $B \in \mathbb{C}^{n,n}$, $\mathfrak{R}(B) = \mathfrak{R}(A)$ implies that $B$ is nonsingular if and only if there exists a permutation matrix $P$ such that $\mathfrak{R}(PA)$ is an $M$-matrix.

The author wishes to acknowledge very helpful correspondence and comments from Professors Maroslav Fiedler, Charles Johnson, Ken Kaneko, James Ortega, Hans Schneider and Richard Varga during the preparation of this survey.
