In Brief

Reverse cholesterol transport (RCT) can be mediated by either the classic biliary route or the nonbiliary transintestinal cholesterolemia (TICE) pathway. Warrier et al. now identify a gut microbial-driven pathway that balances the amount of cholesterol entering the biliary and nonbiliary pathways. Inhibition of the enzyme flavin monooxygenase 3 (FMO3) diverts cholesterol away from biliary excretion into the nonbiliary TICE pathway, reorganizing total body cholesterol balance.

Highlights

- Unbiased transcriptional profiling links FMO3 to reverse cholesterol transport
- FMO3 knockdown substantially impacts whole-body cholesterol balance
- FMO3 is a negative regulator of nonbiliary reverse cholesterol transport
- FMO3 knockdown results in diminished LXR activity, promoting hepatic inflammation

SUMMARY

Circulating levels of the gut microbe-derived metabolite trimethylamine-N-oxide (TMAO) have recently been linked to cardiovascular disease (CVD) risk. Here, we performed transcriptional profiling in mouse models of altered reverse cholesterol transport (RCT) and serendipitously identified the TMAO-generating enzyme flavin monooxygenase 3 (FMO3) as a powerful modifier of cholesterol metabolism and RCT. Knockdown of FMO3 in cholesterol-fed mice alters biliary lipid secretion, blunts intestinal cholesterol absorption, and limits the production of hepatic oxysterols and cholesteryl esters. Furthermore, FMO3 knockdown stimulates basal and liver X receptor (LXR)-stimulated macrophage RCT, thereby improving cholesterol balance. Conversely, FMO3 knockdown exacerbates hepatic endoplasmic reticulum (ER) stress and inflammation in part by decreasing hepatic oxysterol levels and subsequent LXR activation. FMO3 is thus identified as a central integrator of hepatic cholesterol and triacylglycerol metabolism, inflammation, and ER stress. These studies suggest that the gut microbiota-driven TMA/FMO3/TMAO pathway is a key regulator of lipid metabolism and inflammation.

INTRODUCTION

Atherosclerosis and associated cardiovascular disease (CVD) remain the largest causes of mortality in developed countries

(Go et al., 2013). Despite widespread use of statins, CVD-associated mortality and morbidity have been reduced by only ~30% (Go et al., 2013), demonstrating a clear need for better therapeutic strategies. Elevation of high-density lipoprotein (HDL) function is thought to be an attractive therapeutic strategy (Rader and Tall, 2012). However, recent clinical trials (Boden et al., 2011; Schwartz et al., 2012) and Mendelian randomization studies (Voight et al., 2012) have failed to show clinical benefits of HDL cholesterol elevation, calling into question the role of HDL cholesterol as a surrogate marker of protection from atherosclerosis (Rader and Tall, 2012). Both proponents and critics alike of the “HDL hypothesis” agree on one thing: further studies are needed to understand the mechanism regulating the fundamental process of HDL-driven reverse cholesterol transport (RCT). The prevailing model for RCT is that cholesterol from the artery wall is delivered to the liver via HDL, from where it is then secreted into bile before leaving the body through the feces (Dietschy and Turley, 2002; Rader et al., 2009; Rosenson et al., 2012). However, we and others have recently demonstrated that RCT can also proceed through a nonbiliary pathway known as transintestinal cholesterol excretion (TICE), which persists in both the surgical or genetic absence of biliary cholesterol secretion (Temel et al., 2010; Temel and Brown, 2012; Brown et al., 2008; Le May et al., 2013; van der Velde et al., 2007; van der Veen et al., 2009). Under normal physiologic conditions the hepatobiliary route predominates and TICE is a minor pathway, only contributing ~30% of the total cholesterol lost through the feces in mice (Temel and Brown, 2012). However, pharmacologic activation of liver X receptor (LXR) can preferentially stimulate the nonbiliary pathway to where TICE contributes greater than 60% of the total cholesterol lost through the feces (van der Veen et al., 2009). Although mechanisms regulating the classic hepatobiliary pathway of RCT have been well defined (Yu et al., 2002; Graf et al., 2003; Groen et al., 2008; Wiersma

et al., 2009; Temel et al., 2007), almost no mechanistic information exists for the nonbiliary TICE pathway (Temel and Brown, 2012; Brufau et al., 2011).

We have previously described several mouse models where the nonbiliary TICE pathway is either chronically (Temel et al., 2010) or acutely stimulated (Marshall et al., 2014). Here, we have taken advantage of these mouse models as hypothesis-generating tools. To identify regulators of TICE and RCT, we performed transcriptional profiling in NPC1L1-liver-transgenic mice (which exhibit chronic TICE stimulation; Temel et al., 2010) and second generation acyl-coenzyme A: cholesterol acyltransferase 2 (ACAT2) antisense oligonucleotide (ASO)-treated mice (which exhibit acute TICE stimulation; Marshall et al., 2014). From this screening, we found that the hepatic expression of flavin-containing monooxygenase 3 (FMO3) was coordinately downregulated in mouse models of stimulated TICE. In parallel, independent studies have shown that plasma levels of FMO3's product trimethylamine-N-oxide (TMAO) are highly predictive of atherosclerosis in humans, and TMAO is proatherogenic in mice (Wang et al., 2011; Wang et al., 2014; Tang et al., 2013; Koeth et al., 2013; Bennett et al., 2013; Brown and Hazen 2014). Additionally, we have recently shown that dietary supplementation with the FMO3 product TMAO inhibits macrophage RCT in vivo (Koeth et al., 2013). Here we follow up on these collective observations, and demonstrate that FMO3 knockdown stimulates non-biliary macrophage RCT and reorganizes whole body cholesterol balance. The current studies have also uncovered a previously unknown role for FMO3 in regulating hepatic LXR signaling, which controls endoplasmic reticulum (ER) stress and inflammation. Collectively, these observations identify the gut microbiota-driven TMA/FMO3/TMAO pathway as a key integrator of lipid metabolism and immune cell function and specifically identify FMO3 as a key regulator of sterol balance and RCT, independent of its role in TMAO production. Given that this pathway has now been identified in two separate screens (work described here and metabolomics screening by Wang et al., 2011), we believe this pathway represents a central regulatory node for CVD pathogenesis.

RESULTS

Transcriptional Profiling Identifies FMO3 as a Regulator of RCT

To identify potential regulators of macrophage RCT, we performed microarray analysis in liver from two independent mouse models where TICE was either chronically (NPC1L1-liver-transgenic mice; Temel et al., 2010) or acutely (ACAT2 ASO treatment; Marshall et al., 2014) stimulated. With a stringent threshold ($p < 0.001$) set for differentially expressed genes (DEGs), there were less than 100 DEGs within each array data set (Figures 1A and 1B), and the vast majority of DEGs were not coordinately regulated in both cohorts (Tables S1, S2, S3, and S4). In fact, there were only two genes that were coordinately regulated in both models of TICE augmentation (Figures 1C and 1D). The sole gene that was upregulated in both acute and chronic TICE mouse models was Gm10567, which is predicted to be noncoding RNA of unknown biological function (Figure 1C). The only gene that was coordinately downregulated in

both TICE models was FMO3 (Figure 1D; Tables S1 and S2). We subsequently utilized real-time PCR to confirm that FMO3 mRNA expression was significantly reduced in both acute (ACAT2 ASO-treated) and chronic (NPC1L1-liver-transgenic mice) TICE models (Figures 1E and 1F). Interestingly, FMO3 mRNA expression closely reflects the concentration of cholesterol in bile, given that FMO3 expression is significantly reduced in both NPC1L1-liver transgenic mice and in mice with diminished expression of the biliary cholesterol half transporter ABCG8 (data not shown). Given that the FMO3 enzymatic product TMAO has recently been associated with increased CVD risk in humans and shown to both promote atherosclerosis and inhibit RCT in mice (Wang et al., 2011; Tang et al., 2013; Koeth et al., 2013; Bennett et al., 2013; Brown and Hazen, 2014), we decided to further interrogate the primary role of FMO3 in cholesterol balance and RCT.

ASO-Mediated Knockdown of FMO3 Reorganizes Whole-Body Cholesterol Balance

To examine the role of FMO3 in cholesterol balance, we utilized second-generation ASO targeting (Crooke, 1997) in mice fed different levels of dietary cholesterol. FMO3 ASO treatment very effectively reduced hepatic FMO3 mRNA (Figure 2A) and protein (Figure 2B) expression, when compared to mice treated with a nontargeting control ASO. As expected, FMO3 knockdown significantly increased circulating levels of FMO3's substrate trimethylamine (TMA) (Figure 2C), while it reciprocally decreased circulating levels of FMO3's product TMAO (Figure 2D). In parallel, FMO3 knockdown resulted in significant elevations of TMA and reciprocal decreases in TMAO in the liver (data not shown). FMO3 knockdown did not alter the overall health or growth of mice during the period of investigation (data not shown), but it did result in a striking reorganization of cholesterol balance. First, FMO3 knockdown significantly reduced intestinal cholesterol absorption in mice fed a low-cholesterol diet, and it more modestly decreased cholesterol absorption in mice fed a high-cholesterol diet (Figure 2E). Corresponding trends were seen in the mass amount of cholesterol lost in feces, where FMO3 knockdown significantly increased fecal neutral sterol loss in mice fed a low-cholesterol diet, but the trend for increased fecal sterol loss failed to reach significance in FMO3 ASO-treated mice fed a high-cholesterol diet (Figure 2F). In both dietary conditions, FMO3 knockdown significantly reduced hepatic cholesteroyl ester levels (Figure 2G). However, hepatic free cholesterol levels were not altered by diet or ASO treatment (Figure 2H). FMO3 knockdown also reduced the biliary secretion of cholesterol (Figures 2I, S1A, and S1B) and phospholipids (Figures S1E and S1F), without dramatically altering biliary bile acid levels (Figures S1C and S1D). FMO3 ASO-driven reductions in biliary phospholipid were accompanied by significant reductions in the hepatic expression of mdr2 (P-glycoprotein) (data not shown). Finally, FMO3 knockdown did not dramatically alter plasma lipid levels in low-cholesterol-fed mice, but it did cause a modest shift in plasma cholesterol distribution in high-cholesterol-fed mice (Figures 2J–2P). In mice fed a high-cholesterol diet, FMO3 knockdown significantly reduced very low-density lipoprotein (VLDL) cholesterol levels (Figures 2L and 2M) while causing an elevation

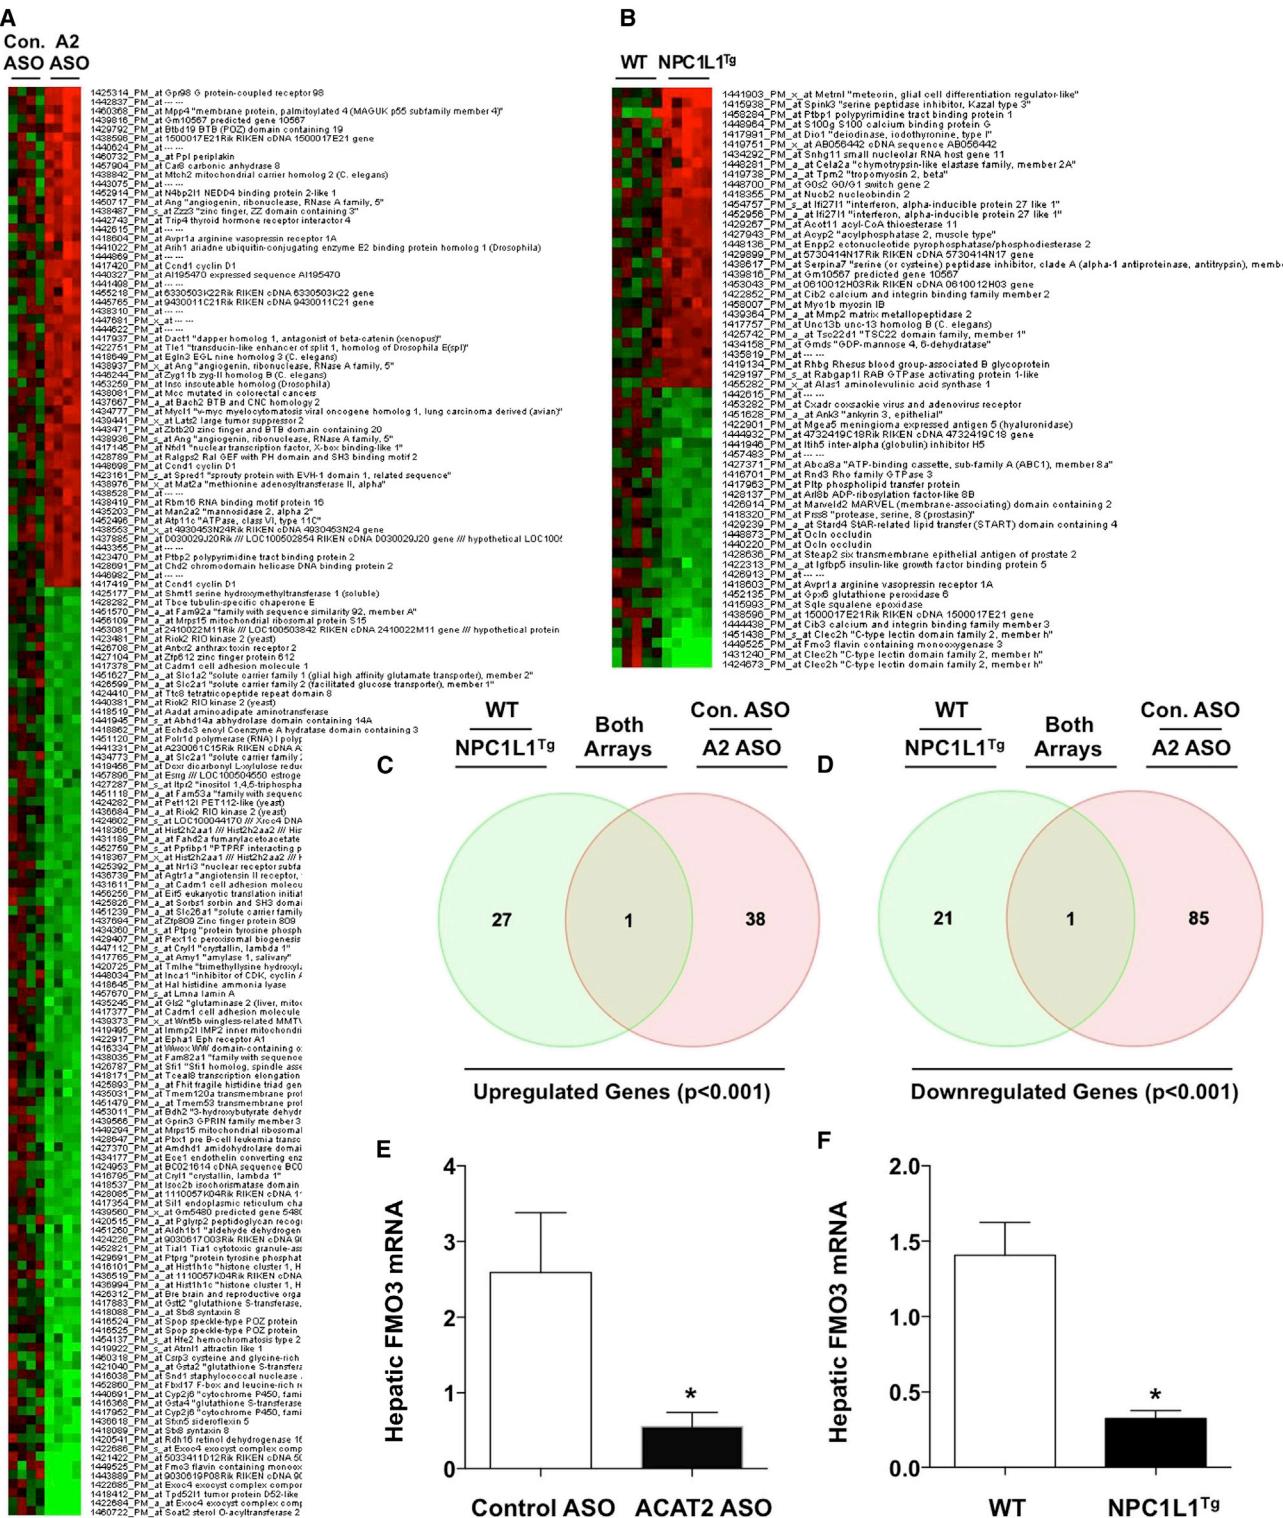

Figure 1. Transcriptional Profiling Defines FMO3 as a Regulator of RCT

(A) Microarray analysis in the acute TICE mouse model. Female C57BL/6 mice were treated with a nontargeting control ASO (Con. ASO) or an ASO targeting ACAT2 mRNA (A2 ASO) as previously described for 1 week (Marshall et al., 2014). Differentially expressed genes (DEGs) are shown as a heatmap (all genes shown have $p < 0.001$, $n = 4$).

(B) Microarray analysis in chronic TICE mouse model. Female wild-type (WT) or NPC1L1-liver transgenic mice (NPC1L1^{Tg}; Temel et al., 2010) were maintained on a high-cholesterol diet (0.2%, w/w) for 8 weeks. Differentially expressed genes (DEGs) are shown as a heatmap (all genes shown have $p < 0.001$, $n = 5$).

(legend continued on next page)

of low-density lipoprotein (LDL) cholesterol levels (Figures 2L and 2N). In contrast, FMO3 knockdown did not alter levels of HDL cholesterol (Figure 2O) or plasma triglycerides (TG) (Figure 2P). Detergent block experiments demonstrated that FMO3 knockdown does not alter VLDL-TG secretion but does blunt VLDL-CE secretion significantly (data not shown). Finally, FMO3 knockdown resulted in a significant reduction of the total bile acid pool size (Figure S2A), which is likely driven by diminished expression of the major bile acid synthetic enzymes Cyp7a1 and Cyp8b1 (Figures S2B and S2C). Collectively, these results show that FMO3 knockdown reorganizes cholesterol balance in a diet-specific manner, indicating a mechanistic link between FMO3 and cholesterol and bile acid metabolism.

FMO3 Coordinates Sterol-Sensing Transcription Factor Activation in the Liver

Cellular cholesterol levels are carefully sensed and regulated by at least two major transcriptional mechanisms involving sterol regulatory element-binding proteins (SREBPs) and liver X receptors (LXRs) (Tontonoz and Mangelsdorf, 2003; Brown and Goldstein, 1999). Interestingly, FMO3 knockdown results in reciprocal regulation of the SREBP and LXR pathways in mouse liver (Figure 3) in a diet-specific manner. In mice fed a low cholesterol diet, where endogenous cholesterol synthesis rates are high, FMO3 knockdown caused significant elevation in SREBP2 target genes including 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase (Figure 3J), HMG-CoA synthase (Figure 3K), and squalene synthase (Figure 3L). In contrast, in mice fed a high-cholesterol diet, where the liver is burdened with excess cholesterol, FMO3 knockdown caused a marked reduction in LXR target genes including ATP binding cassette transporters G5 (Figure 3A) and G8 (Figure 3B), lysophosphatidylcholine acyltransferase 3 (LPCAT3) (Figure 3D), SREBP1c (Figure 3F), fatty acid synthase (Figure 3G), and stearoyl-CoA desaturase 1 (Figure 3H). However, LXR alpha and ATP binding cassette transporter A1 (ABCA1) mRNA expression was not altered by FMO3 knockdown (Figures 3C and 3E). FMO3 ASO-driven alteration in LXR signaling can likely be explained by reduced expression of oxysterol synthetic enzymes Cyp27a1 and Cyp46a1 (data not shown), resulting in decreased availability of endogenous oxysterol ligands in the liver (Figures 3M–3R). Interestingly, circulating oxysterol levels were not similarly altered by FMO3 knockdown, with the exception of the minor oxysterol 25-hydroxycholesterol being slightly elevated (data not shown). In agreement with dampened LXR signaling, FMO3 knockdown strikingly decreased the expression of LXR target genes involved in de novo lipogenesis, and it blunted hepatic steatosis (data not shown). Collectively, these data suggest that FMO3 knockdown depletes hepatic cholesterol stores to a level where SREBP2-driven transcription is activated (Figures 3I–3L) and LXR signaling is reciprocally repressed (Figures 3A–3H) due to diminished oxysterol abundance (Figures 3M–3R).

FMO3 Knockdown Stimulates Nonbiliary Macrophage RCT

Given that FMO3 was coordinately downregulated in both acute and chronic models of TICE (Figure 1), and because prior studies showed TMAO-fed mice had significant reductions in macrophage RCT (Koeth et al., 2013), we wondered whether FMO3 might be linked mechanistically to biliary or nonbiliary RCT. In our macrophage RCT studies, a subset of mice were treated with the LXR agonist T0901317, since it is known that LXR activation promotes macrophage RCT primarily by augmenting the nonbiliary TICE pathway (van der Veen et al., 2009). FMO3 knockdown very modestly decreased total plasma cholesterol levels (Figure 4A). When treated with the LXR agonist T0901317, both control ASO- and FMO3 ASO-treated mice exhibited mild hypercholesterolemia, with the majority of the cholesterol elevation seen in large HDL particles (data not shown), as has been previously described (Grefhorst et al., 2002). Following [³H]-cholesterol-labeled macrophage injection into the peritoneal cavity, the plasma [³H]-cholesterol accumulation was significantly lower in FMO3-inhibited mice, both in the vehicle- and T0901317-treated groups (Figure 4B). This reduction in [³H]-cholesterol was largely due to a decrease in large HDL particles (Figure 4C), which tracked closely with the cholesterol mass distribution (data not shown). Importantly, in control ASO-treated mice, there was an expected increase in LXR agonist-inducible biliary [³H]-cholesterol secretion (Figure 4G). In contrast, FMO3 ASO-treated mice had lower biliary [³H]-cholesterol recovery, both in the vehicle- and T0901317-treated groups, and lacked the expected LXR agonist-inducible response for biliary cholesterol secretion (Figure 4G). Interestingly, FMO3 ASO-treated mice also lack T0901317-induced biliary [³H]-bile acid secretion (Figure 4H). Despite having reduced levels of biliary [³H]-cholesterol (Figure 4G), FMO3 knockdown mice had increased basal and LXR agonist-stimulated disposal of cholesterol into the feces, as measured by both [³H]-cholesterol recovery (Figure 4D) and mass fecal neutral sterol loss (Figure 4F). FMO3 knockdown also modestly increased fecal [³H]-bile acid recovery in both basal and LXR-stimulated conditions (Figure 4E). At the time of necropsy, the hepatic recovery of macrophage-derived [³H]-cholesterol in the form of [³H]-cholesterol (Figure 4I) and [³H]-bile acid (Figure 4J) was not altered by FMO3 knockdown. Likewise, intestinal recovery of macrophage derived [³H]-cholesterol in the form of [³H]-cholesterol (Figure 4K) and [³H]-bile acid (Figure 4L) was not altered by FMO3 knockdown, but there was a slight increase in intestinal [³H]-cholesterol in mice treated with T0901317 (Figure 4K). Interestingly, LXR activation significantly represses hepatic FMO3 mRNA (Figure 4M) and protein (Figure 4N). However, FMO3 knockdown did not dramatically alter canonical LXR-driven target gene expression in the liver and small intestine in these mice maintained on a low-cholesterol diet (data not shown). Of particular relevance to RCT, FMO3 knockdown significantly reduced intestinal NPC1L1 expression (Figure 4O),

(legend continued on next page)

which is in agreement with alterations in intestinal cholesterol absorption (Figure 2E). Collectively, these results demonstrate that FMO3 knockdown promotes both basal and LXR agonist-stimulated macrophage RCT (Figure 4D and 4F) while repressing biliary cholesterol levels (Figures 4G, S1A, and S1B) and intestinal cholesterol absorption (Figure 2E).

FMO3 Knockdown Promotes Hepatic ER Stress and Inflammation by Dampening LXR Activation

LXR activation has previously been shown to dampen both inflammatory responses and ER stress by upregulating direct target genes, such as LPCAT3 (Rong et al., 2013), and transpressing proinflammatory genes, such as iNOS and COX-2 (Joseph et al., 2003). Given that oxysterol ligand availability is lower in FMO3 knockdown mice, we hypothesized that this may promote hepatic inflammation and ER stress. Indeed, FMO3 knockdown caused marked infiltration of macrophages into the liver (Figures 5A and 5B) and increased the expression of macrophage-derived proinflammatory cytokines and chemokines (Figures 5C and 5D). Furthermore, FMO3 knockdown increased the expression of several genes linked to ER stress (ATF3, CHOP) (Figures 5C and 5D) and increased CHOP protein expression (Figure 5E). FMO3 knockdown also increased the activation of c-Src (Figure 5E), which has also recently been linked to saturated fatty acid-induced ER stress and inflammatory signaling (Holzer et al., 2011). Importantly, either providing endogenous LXR agonists (i.e., feeding 0.2% cholesterol in the diet) or providing an exogenous LXR agonist (T0901317) blunted FMO3 ASO-driven hepatic inflammation (Figures 5B–5D), c-Src activation (Figure 5E), and ER stress (Figures 5C–5E). Collectively, these results suggest that FMO3 knockdown promotes hepatic inflammation and ER stress in part by diminishing LXR activity. Collectively, our results are consistent with hepatic FMO3 serving as a critical determinant of the well-known ability of LXR to reciprocally regulate lipid metabolism and inflammation (Joseph et al., 2003; Rong et al., 2013).

FMO3 Gain-of-Function Reciprocally Reorganizes Cholesterol Balance and Hepatic Inflammation

To confirm the specificity of our results with ASO-mediated knockdown of FMO3, we performed parallel gain-of-function experiments by means of adenoviral-mediated gene delivery (Figure S3). Administration of FMO3 adenovirus resulted in an 18-fold increase in hepatic FMO3 mRNA levels (Figure S3A). Hepatic overexpression of FMO3 resulted in modest but significant reductions in fecal neutral sterol loss (Figure S3B) while more substantially increasing biliary cholesterol loss (Figure S3C). Furthermore, FMO3 overexpression resulted in a ~20% increase in total plasma cholesterol levels (Figure S3D). In further agreement with loss-of-function data, FMO3 overexpression significantly reduced the hepatic expression of genes involved in inflammation (CD68, F4/80) and ER stress (ATF3) (Figures

S3E–S3G). FMO3 overexpression also increased expression of the LXR target genes ABCA1 (Figure S3H) and LPCAT3 (Figure S3I). These data further support the notion that FMO3 is a central regulator of cholesterol balance and hepatic inflammatory responses, given that both gain and loss of function impacts the same biochemical pathways.

FMO3 Knockdown Regulates Intestinal Cholesterol Balance in a Gut Microbe-Dependent Fashion

FMO3 has many potential endogenous and xenobiotic substrates (Cashman and Zhang, 2006; Cashman 2008) that could be involved in its ability to regulate cholesterol balance and inflammation. However, we know that the FMO3 substrate TMA and product TMAO are generated solely from gut microbe-dependent metabolism of dietary methylamine nutrients (Wang et al., 2011; Koeth et al., 2013). To determine the involvement of gut microbial metabolites in the ability of FMO3 ASOs to reorganize cholesterol balance and hepatic inflammation, we suppressed gut microbial communities using a poorly absorbed cocktail of antibiotics. After only 1 week of treatment, levels of both the FMO3 substrate TMA and its product TMAO were barely detectable in antibiotic treated mice (Figures S4A and S4B). Interestingly, antibiotic-mediated suppression of gut microbes completely blocked the ability of FMO3 ASO treatment to reduce intestinal cholesterol absorption (Figure S4C) and elevate fecal neutral sterol loss (Figure S4D). However, antibiotic treatment did not significantly alter the ability of FMO3 ASO treatment to increase hepatic CD68 expression (Figure S4F), decrease hepatic FAS expression (Figure S4G), or decrease hepatic Cyp8b1 expression (Figure S4H). Collectively, these results suggest that the ability of FMO3 ASO treatment to alter intestinal cholesterol absorption and fecal neutral sterol excretion likely relies on gut microbial metabolites, of which TMA is a strong candidate, but FMO3 ASO-driven effects on hepatic inflammation, fatty acid synthesis, and bile acid synthesis likely arise from another non-microbial source.

The Ability of FMO3 ASOs to Reorganize Lipid Metabolism and Inflammation Does Not Arise from Diminished TMAO Levels

Given that TMAO has been linked to CVD risk and FMO3 ASO treatment reduces TMAO levels in the circulation and liver (Figure 2D, data not shown), we wanted to determine the involvement of TMAO in the lipid and inflammatory phenotypes seen with FMO3 knockdown. To achieve this, we provided TMAO as a dietary supplement in control and FMO3 ASO-treated mice. As expected, FMO3 knockdown reduced circulating TMAO levels, but dietary TMAO supplementation effectively blocked this effect (Figure S4J). Surprisingly, dietary TMAO supplementation in FMO3-inhibited mice resulted in a marked accumulation of plasma TMA (~80-fold above control levels), likely arising from bacterial conversion of TMAO to TMA (Ansaldi et al., 2007)

coupled with diminished hepatic conversion of TMA into TMAO by FMO3. Despite the ability of dietary TMAO to rescue circulating plasma TMAO levels in FMO3 ASO-treated mice (Figure S4J), this did not alter the ability of FMO3 ASO treatment to alter cholesterol balance (Figures S4K and S4L) or hepatic gene expression (Figures S4M–S4P). Interestingly, in this TMAO add-back experiment, the levels of circulating TMA are positively correlated ($R^2 = 0.45$, $p < 0.0001$) with the amount of fecal neutral sterol loss (data not shown), indicating a potential role for TMA as a gut microbe-derived signal regulating cholesterol balance. Collectively, these data strongly suggest that although chronic elevation of TMAO can be proatherogenic (Wang et al., 2011; Koeth et al., 2013), TMAO is not likely involved in the ability of FMO3 inhibitors to reorganize cholesterol balance and hepatic inflammation.

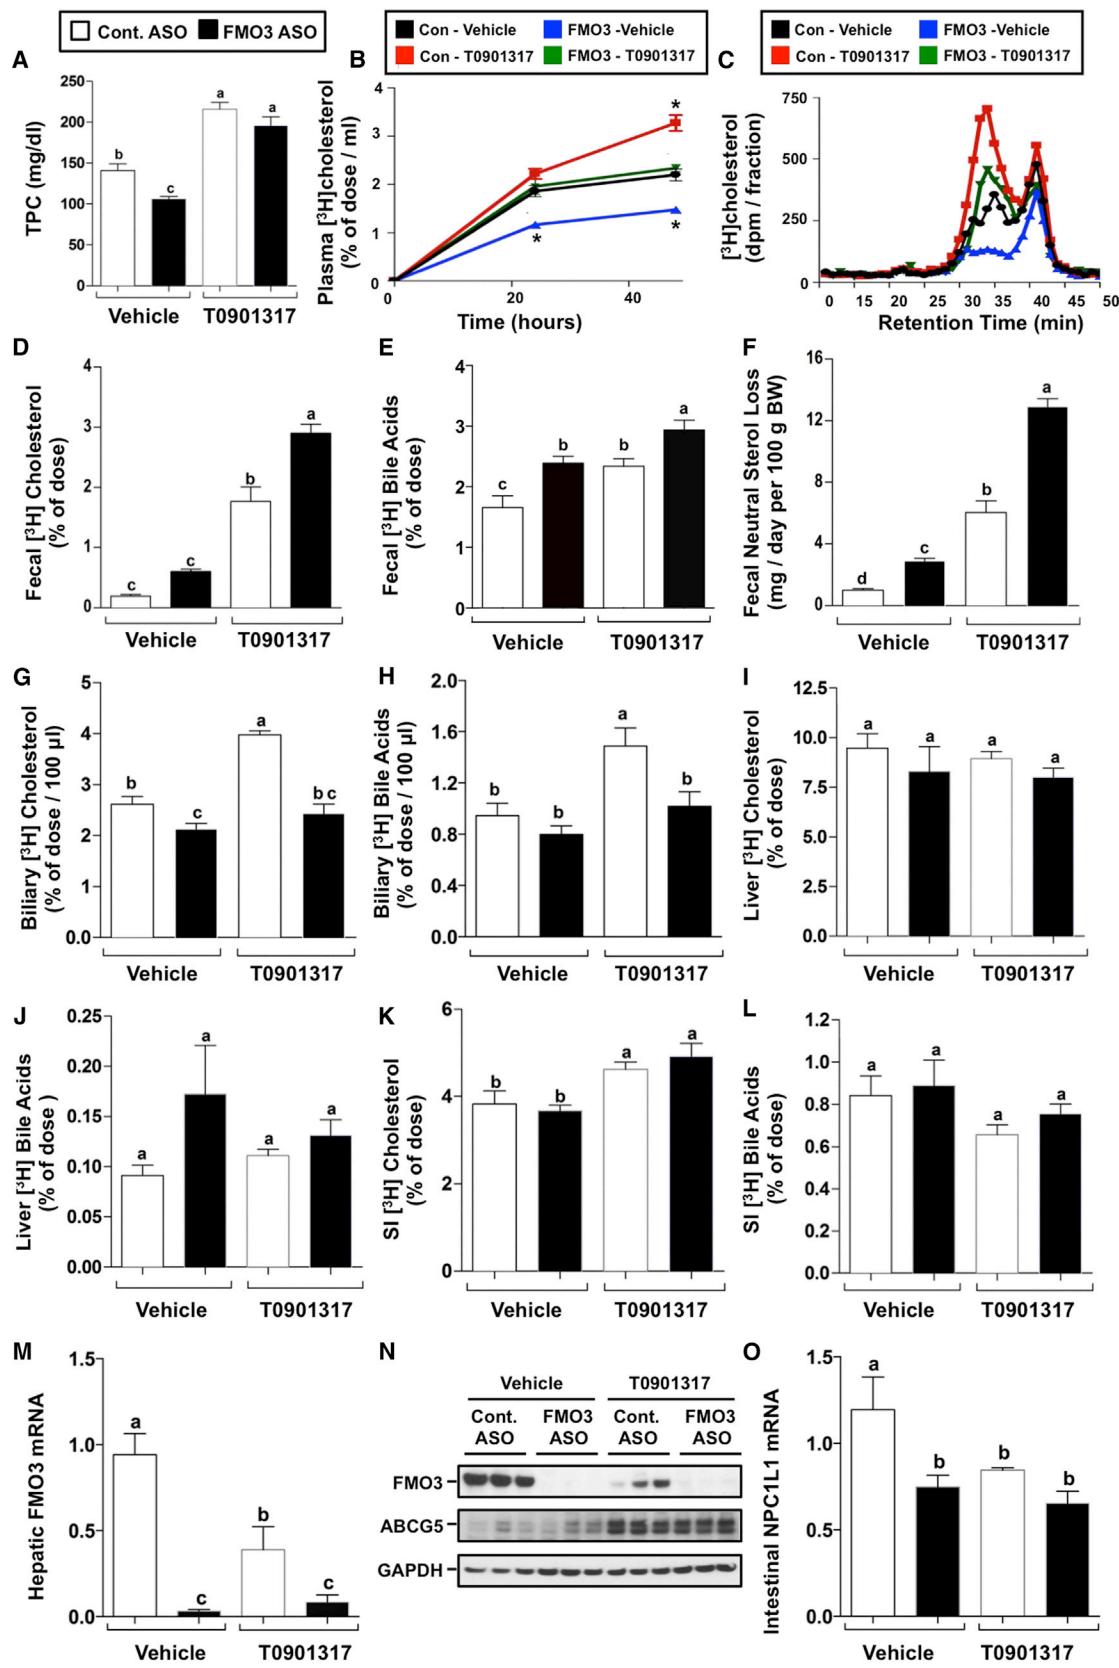

DISCUSSION

Now identified in two independent screens of altered RCT or CVD risk (Figure 1; Wang et al., 2011), the gut microbe-driven TMA/FMO3/TMAO pathway is increasingly being pursued for the treatment or prevention of CVD. However, this pathway exhibits many levels of complexity including dietary inputs (Wang et al., 2011; Koeth et al., 2013), requirement of bacterial metabolism (Brown and Hazen, 2014), and complex hormonal regulation of the FMO enzyme family (Bennett et al., 2013). Furthermore, TMAO feeding (Wang et al., 2011; Koeth et al., 2013) and FMO3 knockdown (data shown here) exert some consistent but many divergent effects on cholesterol and bile acid metabolism across multiple tissues (Figure S5). Although FMO3 and TMAO are directly biochemically connected, our studies suggest that the FMO3 enzyme and the TMAO product likely impact lipid metabolism and inflammation through distinct mechanisms. Therefore it will become increasingly important to differentiate the ability of FMO3 itself versus TMAO to alter the pathogenesis of CVD. The major findings of the current study include the following: (1) transcriptional profiling links FMO3 to RCT, (2) FMO3 knockdown reorganizes multiple processes determining cholesterol balance, (3) FMO3 is a negative regulator of nonbiliary reverse cholesterol transport, (4) FMO3 regulates LXR activity to impact hepatic inflammation and ER stress, (5) FMO3 gain of function reciprocally reorganizes intestinal cholesterol balance and dampens hepatic inflammation, (6) the reorganization of cholesterol balance seen with FMO3 knockdown does not involve TMAO yet can be blocked by antibiotic-mediated suppression of gut microbes, and (7) the hepatic inflammation seen with FMO3 knockdown does not likely involve either TMA or TMAO because it is not suppressed by antibiotics or dietary TMAO. Collectively, these observations identify transcriptional control of FMO3 as an important regulatory switch by which cholesterol balance and hepatic inflammatory responses are integrated.

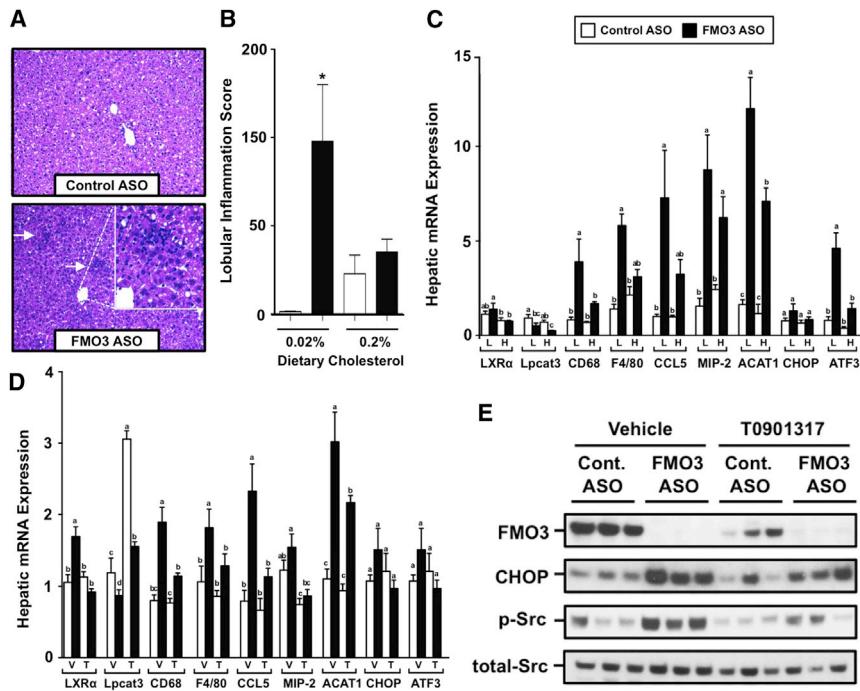

Given that normalization of circulating TMAO levels in FMO3-inhibited mice does not rescue the abnormal lipid and inflammatory phenotype, it is likely that other FMO3 substrates or products are involved. An obvious candidate would be the accumulation of the FMO3 substrate TMA in FMO3 ASO-treated mice. Two pieces of evidence support that TMA may be involved

in the ability of FMO3 to regulate cholesterol balance: (1) antibiotic treatment, a condition that causes disappearance of circulating TMA, blocks the ability of FMO3 ASO treatment to blunt intestinal cholesterol absorption and increase fecal cholesterol loss (Figures S4C and S4D); and (2) circulating TMA levels significantly correlate with the level of fecal neutral sterol loss (data not shown). Although these data suggest a potential role for TMA in regulating cholesterol balance, there is no similar support for TMA being involved in the hepatic inflammation seen in FMO3-inhibited mice given that antibiotic treatment does not reverse FMO3 ASO-driven hepatic inflammation. Furthermore, the ability of FMO3 knockdown to suppress genes involved in hepatic lipogenesis (FAS, ACC1, SCD1) does not involve the TMA/TMAO axis, given that antibiotic treatment or dietary TMAO supplementation do not reverse FMO3 ASO-driven repression of these genes (Figure S4). Collectively, these data suggest that the ability of FMO3 inhibitors to alter cholesterol balance, inflammation, and ER stress likely involves several molecular mechanisms including gut microbial metabolism (alterations in cholesterol absorption and fecal neutral sterol loss) and gut microbe-independent mechanisms (alterations in hepatic inflammation, ER stress, and lipogenesis). Therefore, it will become increasingly important to identify and consider all potential substrates and products (both natural products and xenobiotics) of FMO3 that have the potential to reorganize these diverse phenotypes. Identification of such FMO3-regulated substrates and products could create untapped therapeutic opportunities for lipid- or inflammation-driven diseases.

Our discovery of FMO3 as a coordinately downregulated gene in acute and chronic TICE models (Figure 1) lead us to hypothesize that FMO3 may be a key integrator of biliary and nonbiliary RCT. To our surprise, FMO3 knockdown actually phenocopies our chronic TICE mouse model (NPC1L1-liver-transgenic mice), which displays severely reduced biliary cholesterol levels with normal fecal cholesterol loss (Temel et al., 2010). Much like NPC1L1-liver-transgenic mice (Temel et al., 2010), FMO3-inhibited mice seem to preferentially utilize the nonbiliary TICE pathway for fecal disposal of cholesterol (Figure 4). In particular, FMO3 ASO treatment strongly enhances LXR agonist-driven macrophage RCT into the feces (Figure 4D) while at the same time preventing LXR agonist-driven increases in biliary cholesterol (Figure 4G). This observation is important because LXR agonists preferentially stimulate the nonbiliary TICE pathway (van der Veen et al., 2009), further supporting FMO3 as a negative regulator of TICE. It is interesting to note that treatment with the LXR agonist T0901317 in control ASO-treated mice significantly reduces hepatic FMO3 mRNA (Figure 4M) and FMO3 protein (Figure 4N). These data demonstrate that now in three independent conditions where TICE is stimulated (van der Veen et al., 2009; Temel et al., 2010; Marshall et al., 2014), FMO3 is transcriptionally repressed (Figures 1, 4M, and 4N). Collectively, these findings demonstrate that FMO3 gene expression is coordinately repressed in several mouse models of augmented TICE and that FMO3 knockdown promotes basal and LXR agonist-stimulated nonbiliary RCT (Figure 4). However, it is important to point out that since multiple steps of cholesterol balance are altered by FMO3 knockdown, it is difficult to interpret which step predominates to promote RCT and whether the

reorganization of cholesterol balance seen in FMO3 knockdown mice is derived simply from alterations in TICE. For instance, by inhibiting cholesterol absorption (Figure 2E), FMO3 knockdown could indirectly impact both biliary and nonbiliary macrophage RCT rates (Sehayek and Hazen, 2008; Jakulj et al., 2010). Therefore, although FMO3 knockdown does clearly reorganize the biliary and nonbiliary RCT pathways toward TICE predominance,

it also alters multiple steps of forward and reverse cholesterol transport, culminating in a net-negative cholesterol balance.

It has long been known that a complex reciprocal relationship exists between many lipid metabolic and inflammatory pathways. This antagonism, collectively known as transrepression, is orchestrated by crosstalk between several nuclear hormone receptors (GR, PPAR α , PPAR γ , PPAR δ , LXR α , NURR1, etc.)

Figure 4. FMO3 Knockdown Stimulates Nonbiliary Macrophage RCT

Female C57BL/6 mice were fed a low-cholesterol (0.02%, w/w) diet and treated with either a control (nontargeting) ASO or an ASO targeting FMO3 mRNA for 6 weeks. During the last week of treatment, mice were also orally gavaged with either a vehicle or an exogenous LXR agonist (T0901317). During the last 48 hr, mice were singly housed, and macrophage RCT into different compartments was measured as described in Experimental Procedures.

All data represent the mean ± SEM from six to ten mice per group, and means not sharing a common superscript differ significantly ($p < 0.05$).

Figure 5. FMO3 Knockdown Promotes Hepatic Inflammation and ER Stress by Dampening LXR Activation

For dietary cholesterol-induced LXR activation (A–C), female C57BL/6 mice were fed either a low- (0.02%, w/w) or high-cholesterol (0.2%, w/w) diet and treated with either a control (nontargeting) ASO or an ASO targeting knockdown of FMO3 for 6 weeks. For exogenous ligand-induced LXR activation (D and E), female C57BL/6 mice were fed a low-cholesterol (0.02%, w/w) diet and treated with either a control (nontargeting) ASO or an ASO targeting FMO3 mRNA for 6 weeks. During the last week of treatment, mice also were orally gavaged with either a vehicle or an exogenous LXR agonist (T0901317) as described in the macrophage RCT experiments in Experimental Procedures.

(A) H&E-stained liver sections (200 \times magnification) from female C57BL/6 mice fed a low-cholesterol (0.02%, w/w) diet and treated with either a control ASO or an FMO3 ASO for 6 weeks. Arrows indicate areas of localized immune cell infiltration.

and the proinflammatory master transcription factor NF- κ B (Glass and Sajio, 2010; Joseph et al., 2003; Khovidhunkit et al., 2003). Activation of diverse nuclear hormone receptors (GR, PPAR α , PPAR γ , PPAR δ , LXR α , NURR1, etc.) can transrepress T cell- and macrophage-driven inflammatory responses orchestrated by NF- κ B, while in a reciprocal manner, activation of NF- κ B-driven proinflammatory signaling effectively blunts nuclear hormone receptor signaling (Glass and Sajio, 2010; Joseph et al., 2003; Khovidhunkit et al., 2003). Relevant to our work, LXR activation can strongly suppress NF- κ B-driven cytokine and chemokine responses to a multitude of inflammatory stimuli (Joseph et al., 2003; Glass and Sajio, 2010). This transrepression pathway likely underlies the hepatic inflammation and ER stress seen with FMO3 knockdown (Figure 5). Recently, it was demonstrated that a direct transcriptional target of LXR (LPCAT3) mediates a large part of this transpressive pathway (Rong et al., 2013). Here, we show that FMO3 activity is a major determinant of both LXR activation (Figure 3) and downstream anti-inflammatory responses in the liver. Our data suggest that the TMA/FMO3/TMAO pathway is a previously underappreciated regulator of LXR activity, which has broad implications in sterol balance and inflammatory processes.

Given that the link between the metaorganismal TMAO pathway and CVD has only been established in the last 3 years, many additional studies are required to gain insights into where therapeutic interventions should be targeted. The studies described here, along with previous reports linking TMAO to CVD risk in humans (Wang et al., 2011, 2014; Tang et al., 2013; Koeth et al., 2013), provide compelling evidence that the TMA/FMO3/TMAO pathway is a central regulatory pathway that deserves further exploration. However, the ability of TMAO to promote atherosclerosis (Wang et al., 2011, 2014; Tang et al., 2013; Koeth et al., 2013) may be mutually exclusive from the ability of FMO3 inhibitors to reorganize cholesterol balance and hepatic inflammation. Our studies highlight the necessity to understand the repertoire of substrates that can be utilized by FMO3 and also open the possibility that FMO3 may have regulatory functions distinct from its enzymatic activity. Given that FMO3 knockdown and gain of function reciprocally reorganize cholesterol balance, inflammation, and ER stress, FMO3 is uniquely positioned among the FMO family of enzymes to impact human disease. However, further studies are warranted to determine whether this pathway can be exploited pharmacologically in lipid- or inflammatory-driven disease. In particular identification of FMO3 substrates and products that play a primary role in promoting nonbiliary macrophage RCT, without increasing hepatic inflammation, would be an attractive strategy for innovative cholesterol lowering drugs in the poststatin era. Advancement in our understanding of the enzymology of FMO3 is thus not only predicted to be informative in xenobiotic toxicology studies but also may provide insights into therapeutic strategies for the treatment or prevention of atherosclerosis.

EXPERIMENTAL PROCEDURES

Animal Studies

The acute and chronic TICE mouse models used for screening purposes have been previously described (Marshall et al., 2014; Temel et al., 2010). For ASO-

mediated knockdown of FMO3, female C57BL/6 mice were maintained on either low- (0.02%) or high-cholesterol (0.2%) diets for a period of 6 weeks and simultaneously injected with control (nontargeting) or FMO3-targeting ASOs biweekly (25 mg/kg body weight) as previously described (Marshall et al., 2014). Macrophage RCT experiments were done as previously described (Temel et al., 2010). All methods used for lipid biochemistry (quantification of cholesterol, oxysterols, bile acids, and phospholipids) have been previously described (Marshall et al., 2014; Koeth et al., 2013; Thomas et al., 2013). All mice were maintained in an American Association for Accreditation of Laboratory Animal Care-approved animal facility, and all experimental protocols were approved by the Institutional Animal Care and Use Committee at Wake Forest University School of Medicine and the Cleveland Clinic Lerner Research Institute.

RNA and Protein Methods

Tissue RNA extraction, real-time PCR, and microarray analyses were performed as previously described (Thomas et al., 2013; Marshall et al., 2014). Immunoblotting was conducted as previously described (Thomas et al., 2013). A detailed description of RNA and protein methods is available in *Supplemental Experimental Procedures*.

Statistical Analysis

Most data are expressed as the mean \pm SEM and were analyzed using either a one-way or a two-way ANOVA followed by Student's t tests for post hoc analysis using JMP version 5.0.12 software (SAS Institute). For microarray analysis, we used empirical Bayes method implemented in R package limma (Smyth 2004).

ACCESSION NUMBERS

The GEO accession number for the data reported in this paper is GSE64326.

SUPPLEMENTAL INFORMATION

Supplemental Information includes Supplemental Experimental Procedures, five figures, and four tables and can be found with this article online at <http://dx.doi.org/10.1016/j.celrep.2014.12.036>.

AUTHOR CONTRIBUTIONS

J.M.B. planned the project, designed experiments, analyzed data, and wrote the manuscript; J.M.B., R.E.T., and S.L.H. designed experiments and provided useful discussion directing the project; M.W., D.M.S., A.C.B., D.F., A.D.G., A.L.B., S.M., A.M., R.C.S., Z.W., J.S., and J.C. conducted mouse experiments, analyzed data, and aided in manuscript preparation; R.G.L., R.M.C., and M.J.G. provided antisense oligonucleotides and valuable discussion; I.M., V.L., C.H., U.T., and R.Z. performed all *in vitro* enzyme assays and provided valuable discussion; X.L. provided histopathological reports; X.R., T.d.A.V., D.M.S., P.T., and A.J.L. performed adenoviral overexpression studies in mice; Z.W., S.L.H., P.P., P.T.I., D.S.M., and H.A.B. performed mass spectrometric analyses and provided critical insights for these studies; and all authors were involved in the editing of the final manuscript.

ACKNOWLEDGMENTS

This work was supported by NIH and Office of Dietary Supplements grants R00 HL096166 (J.M.B.), R01 HL122283 (J.M.B.), R01 HL103866 (S.L.H.), P20 HL113452 (S.L.H.), and U54 GM069338 (H.A.B.). Additional support was provided by American Heart Association grants 14POST18700001 (M.W.) and 14SDG18440015 (T.d.A.V.). Further support was provided by the Cleveland Clinic Foundation General Clinical Research Center of the Cleveland Clinic/Case Western Reserve University CTSA (1UL1RR024989). S.L.H. is also partially supported by a gift from the Leonard Krieger Fund. The authors thank Stephen Milne for assistance with the glycerophospholipid mass spectrometry analysis. Some of the mass spectrometry studies were performed in the Lerner

Research Institute Mass Spectrometry Core, with instruments partially supported by a Center of Innovation Award by AB Sciex.

S.L.H. and Z.W. are named as coinventors on pending and issued patents held by the Cleveland Clinic relating to cardiovascular diagnostics and therapeutics and have the rights to receive royalty payments for inventions or discoveries related to cardiovascular diagnostics. S.L.H. has been paid as a consultant by Cleveland Heart Lab, Esperion, Liposciences, and Procter & Gamble and has received research funds from Cleveland Heart Lab, Esperion, Liposciences, Proctor & Gamble, Roche, and Takeda. Richard Lee, Rosanne Crooke, and Mark Graham are employees at Isis Pharmaceuticals (Carlsbad, CA).
