Results: The serum C (250.9±38.5 vs. 167.0±24.5mg/dL P<0.05) and LDL-C (170.7±52.2 vs. 123.8±18.0mg/dL P<0.05) decreased significantly after A. However, no significant elevation of C and LDL-C was noted after withdrawal of A. The VACM-1 and ISO were significantly increased to 591.18±203.65ng/ml and 12.34±4.53ng/ml respectively at day 2 after withdrawal of A. The IP-A decreased significantly to 9.92±8.67ng/ml at day 3.

Conclusion: After 12 wks of A, the positive pleotropic effects of Astatine are demonstrated simultaneously with lowering the serum C. However, after withdrawal of A, these pleiotropic effects are significantly abrogated within days and are independent on the elevation of serum C.

Prevalence of Risk Factors for Coronary Disease in Myocardial Infarction in the Community
Francisco Lopez-Jimenez, Steven J. Jacobsen, Guy S. Reeder, Susan A. Weston, Jill M. Killian, Ryan Mouenmud, Valerie H. Rogers, Maryl Ciljin, Rochester, MN

While reports suggest that the prevalence of cardiovascular risk factors (CV RF) in acute myocardial infarction (MI) may be low, there is a paucity of data on the prevalence of modifiable CV RF among patients with MI in a geographically defined population, and it is not known whether the prevalence is changing over time.

OBJECTIVE: To determine the overall prevalence of CV RF among patients with MI in the population and their changes over time.

DESIGN: Population-based MI incidence cohort.

METHODS: We analyzed the prevalence of major modifiable CV RF including overweight/obesity, history of smoking, diabetes mellitus, hypertension and hyperlipidemia; and non-modifiable CV RF including age>75 yrs, male sex or family history of coronary disease among all residents of Olmsted County, MN, hospitalized for a validated incident MI between 1979 and 1999. Demographic and clinical characteristics were collected from community medical records.

RESULTS: During the study period, 2,277 subjects had a MI. Only 3.6% of patients did not have modifiable CV RF. When compared to patients with a MI from 1979-63, patients who had the MI from 1994-98 were more likely to be overweight/obese (72% vs. 58%; p<0.05), to have a history of smoking 95% vs. 70%; to be male, 55% vs. 61%, all with a P<0.05 including the four 5-year groups. There was no difference in the prevalence of diabetes, family history of coronary disease or being >75 yrs old. In patients >75 yrs of age, those who had a MI from 1994-98 were 72% more likely to be obese (BMI ≥30 Kg/m2) 43% vs. 26%, and either overweight or obese, 82% vs. 70%; and more likely to have a history of smoking, 95% vs. 70%; or to be male, 55% vs. 61%, all with a P<0.05 including the four 5-year groups. There was no difference in the prevalence of diabetes, family history of coronary disease or being ≥75 yrs old. In patients ≥75 yrs of age, those who had a MI from 1994-98 were 72% more likely to be obese (BMI ≥30 Kg/m2) 43% vs. 26%, and either overweight or obese, 82% vs. 70%; and more likely to have a history of smoking, 95% vs. 70%; or to be male, 55% vs. 61%, all with a P<0.05 including the four 5-year groups.

845-1 The Influence of the Metabolic Syndrome on 24-Year Mortality Among Middle-Aged Men in the Multiple Risk Factor Intervention Trial (MRFIT)
Jerome D. Cohen, Lynn E. Eberly, Ronald Prineas, Gabriela Vasquez. MRFIT Research Group, Saint Louis University, St. Louis, MO, University of Minnesota, Minneapolis, MN

Background. The Metabolic Syndrome (MS) has been recently defined and identified as an important clustering of risk factors for cardiovascular disease (CVD). We explored the long-term mortality of men with MS and with or without concurrent untreated diabetes mellitus (DM).

Methods: 12,517 men who participated in the MRFIT were classified according to base-line presence of MS and/or DM not on hypoglycemic agents. MS was defined as three or more of: body mass index ≥30 kg/m², triglycerides ≥150 mg/dl, high-density-lipoprotein cholesterol <40 mg/dl, blood pressure ≥130/85 mm Hg, and fasting glucose ≥110 mg/dl. Untreated DM was defined as fasting glucose ≥126 mg/dl and not on hypoglycemic agents. Proportional hazards regression models were fit for total and CVD mortality with adjustment for age, race, cigarette smoking, alcohol drinks, total cholesterol, uric acid, and medication treated group (intervention vs. no intervention), using Cox proportional hazard regression, regression for level of education counseling to lower cholesterol, and hypertension medication; corrected using S ion-physician).

Results: A. 71% men had MS only, 37% had DM only, and 55% had both. 43 men on hypoglycemic agents were excluded. There were 4,556 total and 2,221 CVD deaths over the median follow-up of 24.4 years. Average blood pressure was reduced from 135/9 mm Hg at baseline to 124/82 after 6 years; average cholesterol was reduced from 240 to 231 mg/dl. Adjusted hazard ratios (HR) for CVD mortality relative to those with neither MS nor DM, were 1.27 for those with MS only [p=0.0001], 1.37 for those with DM only [p=0.08], and 1.99 for those with both MS and DM [p=0.0001]. Results were similar for total mortality with HRS of 1.15 [p=0.0001], 1.63 [p=0.01], and 1.68 [p=0.0001] respectively.

Conclusions: The presence of MS with or without untreated DM was associated with a significantly increased risk in mortality compared to those with neither MS nor DM. Thus the treatment of MS and its individual components are an important part of the strategy for the prevention of CVD.

845-2 Niacin Decreases Myocardial Infarction and Total Mortality in Patients With Metabolic Syndrome: Results From the Coronary Drug Project
Paul L. Canner, Curt D. Furberg, Michael L. Trenn, Mark E. McGovern, Maryland Medical Research Institute, Baltimore, MD, Wake Forest University, Winston-Salem, NC

Background: In the Coronary Drug Project (CDP), niacin decreased recurrent nonfatal myocardial infarction (NFM) by 28% at 6 years (study end) and total mortality by 11% at 15 years (9 years post-trial). Since niacin may affect insulin sensitivity, and new national guidelines emphasize the importance of metabolic syndrome (MS), we evaluated whether niacin's effects on clinical outcomes were similar in patients with and without MS.

Methods: We defined MS as at least 3 of triglycerides ≥150 mg/dl, blood pressure ≥130/85 mm Hg, fasting glucose ≥110 but <126 mg/dL, or body mass index ≥28 as a substitute for waist circumference. High-density-lipoprotein cholesterol (HDL-C) had been measured in a small number of patients (N=492), so we made a secondary analysis of HDL-C 40 mg/dl as a cutoff for MS. Relative hazards (RH) and Z-values for homogeneity of treatment effect between subgroups were computed.

RESULTS: Results are shown below. The Z-values for homogeneity indicate no significant difference in effect between patients with and without MS. We therefore analyzed results in this subgroup from CDP using National Cholesterol Education Program Adult Treatment Panel III criteria.

Methods: We defined MS as at least 3 of triglycerides ≥150 mg/dl, blood pressure ≥130/85 mm Hg, fasting glucose ≥110 but <126 mg/dL, or body mass index ≥28 as a substitute for waist circumference. High-density-lipoprotein cholesterol (HDL-C) had been measured in a small number of patients (N=492), so we made a secondary analysis of HDL-C ≥40 mg/dl as a cutoff for MS. Relative hazards (RH) and Z-values for homogeneity of treatment effect between subgroups were computed.

Conclusions: The presence of MS with or without untreated DM was associated with a significantly increased risk in mortality compared to those with neither MS nor DM. Thus the treatment of MS and its individual components are an important part of the strategy for the prevention of CVD.

Conclusion: The Metabolic Syndrome is an Independent Predictor of Cardiac Events in WOSCOPS Males

Gilbert L. Dahlen, Ian Ford, James Shepherd, Irwin Myers-Squibb, Watlington, U.L., University of Glasgow, Glasgow, United Kingdom

Background: The Metabolic Syndrome (METS) is characterized by component conditions of dyslipidemia, hypertension, insulin resistance, and obesity. Although the syndrome is recognized as a CHD risk equivalent by the ATP III guidelines committee, there
