Highly oscillatory integrals
Filon quadrature

#### Abstract

We analyze the convergence behavior of Filon-type quadrature rules by making explicit the dependence on both $k$, the parameter that controls the oscillatory behavior of the integrand, and $n$, the number of function evaluations. We provide explicit conditions on the domain of analyticity of the integrand to ensure convergence for $n \rightarrow \infty$.

## 1. Introduction and Filon-type quadrature

For a given $k \in \mathbb{R}$ with $|k|$ large, we seek to evaluate

$$
\begin{equation*}
Q(f):=\int_{-1}^{1} \mathrm{e}^{\mathrm{i} k g(x)} f(x) \mathrm{d} x \tag{1}
\end{equation*}
$$

Here, $f$ and $g$ are assumed to satisfy:
Assumption 1.1. $\mathcal{g}_{g} \subset \mathcal{G}_{f} \subset \mathbb{C}$ are open neighborhoods of $[-1,1]$. The function $f \in L^{\infty}\left(\mathcal{G}_{f}\right)$ is holomorphic on $\mathcal{G}_{f}$, the function $g$ is real-valued on $[-1,1], g^{\prime} \neq 0$ on $[-1,1], g$ and $1 / g^{\prime}$ are holomorphic on $\mathcal{g}_{g}$, and $1 / g^{\prime} \in L^{\infty}\left(\mathcal{g}_{g}\right)$.

Filon-type quadrature (see [1-3]) assumes that integrals $\int_{-1}^{1} \mathrm{e}^{\mathrm{ikg}(x)} \pi(x) \mathrm{d} x$ can be evaluated for polynomials $\pi$. Hence, a quadrature rule for the integral (1) can be obtained by replacing the integrand $x \mapsto \mathrm{e}^{\mathrm{i} k g(x)} f(x)$ with $x \mapsto \mathrm{e}^{\mathrm{i} k g(x)} I_{\Delta} f(x)$, where $I_{\Delta} f$ is a polynomial (Hermite)interpolant of $f$; that is, we obtain the Filon-type quadrature rule

$$
\begin{equation*}
Q_{\Delta}(f):=\int_{-1}^{1} \mathrm{e}^{\mathrm{i} k g(x)} I_{\Delta} f(x) \mathrm{d} x \tag{2}
\end{equation*}
$$

Throughout this note, we will associate with a sequence $\Delta=\left(z_{0}, \ldots, z_{n}\right)$ of $n+1$ nodes the (Hermite)interpolation operator $I_{\Delta}$ that maps $f$ to the polynomial $I_{\Delta} f \in \mathscr{P}_{n}$ of degree $n$ that interpolates in the $n+1$ nodes; the implicit understanding of Hermite interpolation is that if a node $\xi$ appears $m+1$ times in $\Delta$, then $\left(f-I_{\Delta} f\right)^{(j)}(\xi)=0$ for $j=0, \ldots, m$.

For a sequence $\left(\Delta^{n}\right)_{n=0}^{\infty}$ of interpolation points $\Delta^{n}=\left(z_{0}^{(n)}, \ldots, z_{n}^{(n)}\right)$ we can study the convergence behavior of $Q(f)-Q_{\Delta^{n}}(f)$ as a function of $k$ and $n$. This analysis is the purpose of the present note.

It is well known that for large $|k|$, the most important contribution to the integral comes from the endpoints. Hence, it is sensible to include as much endpoint information in the choice of the interpolant $I_{\Delta} f$ as possible. The extreme case is to take $I_{\Delta}$ as the interpolation operator of Hermite type associated with the endpoints $\pm 1$; that is, $\Delta=\Delta_{H}^{2 p-1}=$ $(-1, \ldots,-1,1, \ldots, 1)$, where each of the nodes $\pm 1$ appears $p$ times. The Filon quadrature $Q_{\Delta_{H}}^{2 p-1}$, which we call "pure

[^0]Filon quadrature" in this note, is shown to satisfy

$$
\begin{equation*}
\left|Q(f)-Q_{\Delta_{H}^{2 p-1}}(f)\right| \leq C \min \left\{q, \frac{\gamma(p+1)}{|k|}\right\}^{p+1} \tag{3}
\end{equation*}
$$

for some constants $C, q, \gamma>0$ independent of $k$ and $p$ (combine Theorems 2.1 and 2.2). The parameter $q$ is in general $\geq 1$ so that convergence as $p \rightarrow \infty$ is not guaranteed-however, good approximations can be expected if $|k|$ is large compared to $p$. Theorem 2.2 gives explicit conditions on the domains of analyticity of $f$ and $g$ to ensure $q \in(0,1)$, namely:

Assumption 1.2. In addition to Assumption 1.1, the domain $g_{f}$ satisfies

$$
\begin{equation*}
\mathscr{G}_{f} \supset W_{r}^{H} \quad \text { for some } r>1, \quad W_{r}^{H}:=\left\{z \in \mathbb{C}| | z^{2}-1 \mid<r^{2}\right\} \tag{4}
\end{equation*}
$$

If Assumption 1.2 is satisfied, then $q \in(0,1)$ in (3) so that the pure Filon quadrature is a convergent (as $p \rightarrow \infty$ ) method whose preasymptotic behavior improves as $|k|$ becomes large.

Assumption 1.2 is seen in numerical examples (see Section 4) to be necessary for convergence of the pure Filon quadrature. Section 3.1 shows that the limitations imposed by Assumption 1.2 can be overcome with composite quadrature rules; an alternative, discussed in Section 3.2, is to insert additional quadrature points in the interior of the integration domain. Section 2.3 finally shows that by suitably clustering the quadrature points near the endpoints, Filon-type quadrature rules can be designed that do not require derivative information but still lead to convergent methods under Assumption 1.2.

Concluding this introduction, we mention that our analysis ignores several important aspects: Firstly, we do not discuss the issue of numerical stability; in particular, our numerical experiments in Section 4 are done in Maple with high precision arithmetic. Secondly, we skirt the so-called moment problem, i.e., the question of how to evaluate integrals $\int_{-1}^{1} \mathrm{e}^{\mathrm{i} k g(x)} \pi(x) \mathrm{d} x$ for polynomials $\pi$; one option is to use the classical method of steepest descent coupled with Gauß-Laguerre quadrature (see, e.g., [4] for a recent account of this procedure). Concerning notation: $B_{\delta}(z) \subset \mathbb{C}$ denotes an (open) ball of radius $\delta$ centered at $z$; for sets $A \subset \mathbb{C}$, we set $B_{\delta}(A):=\bigcup_{z \in A} B_{\delta}(z)$.

### 1.1. Reduction to interpolation error analysis

The simplest quadrature error estimate is

$$
\begin{equation*}
\left|Q(f)-Q_{\Delta}(f)\right|=\left|Q\left(f-I_{\Delta} f\right)\right| \leq\left\|f-I_{\Delta} f\right\|_{L^{1}(-1,1)} \leq 2\left\|f-I_{\Delta} f\right\|_{L^{\infty}(-1,1)} \tag{5}
\end{equation*}
$$

Integration by parts yields sharper bounds in terms of $k$ :
Lemma 1.3. Let Assumption 1.1 be valid. Set $\gamma_{g}:=\left\|1 / g^{\prime}\right\|_{L^{\infty}\left(g_{g}\right)}$. Let $\Delta=\left(z_{0}, \ldots, z_{n}\right) \subset[-1,1]$ be given. Let $J_{0} \in \mathbb{N}_{0}$ be such that $\left(f-I_{\Delta} f\right)^{(j)}( \pm 1)=0$ for $j=0, \ldots, J_{0}-1$. Then, for every $J \in \mathbb{N}_{0}$ and $0<\delta \leq \operatorname{dist}\left(\{ \pm 1\}\right.$, $\left.\partial g_{g}\right)$ and $0<d \leq \operatorname{dist}\left([-1,1], \partial \mathcal{g}_{g}\right):$

$$
\left|Q(f)-Q_{\Delta}(f)\right| \leq \frac{\gamma_{g}}{|k|} \sum_{j=J_{0}}^{J-1}\left(\frac{j \gamma_{g}}{|k| \delta}\right)^{j}\left\|f-I_{\Delta} f\right\|_{L^{\infty}\left(B_{\delta}(\{ \pm 1\})\right)}+\left(\frac{J \gamma_{g}}{d|k|}\right)^{J}\left\|f-I_{\Delta} f\right\|_{L^{\infty}\left(B_{d}([-1,1])\right)} .
$$

Proof. Let $\eta_{0}:=f-I_{\Delta} f$ and define the sequence $\left(\eta_{j}\right)_{j=0}^{\infty}$ of holomorphic functions by the recursion

$$
\begin{equation*}
\eta_{j+1}=\left(\frac{1}{g^{\prime}} \eta_{j}\right)^{\prime}, \quad j=0,1, \ldots \tag{6}
\end{equation*}
$$

Integrating $Q(f)-Q_{\Delta}(f)=Q\left(f-I_{\Delta} f\right)=Q\left(\eta_{0}\right)$ by parts $J \in \mathbb{N}_{0}$ times gives

$$
\begin{equation*}
Q\left(\eta_{0}\right)=\left.\frac{1}{\mathbf{i} k} \sum_{j=0}^{J-1}\left(\frac{-1}{\mathbf{i} k}\right)^{j} \mathrm{e}^{\mathbf{i} k g} \frac{\eta_{j}}{g^{\prime}}\right|_{-1} ^{1}+\left(\frac{-1}{\mathbf{i} k}\right)^{J} \int_{-1}^{1} \mathrm{e}^{\mathrm{i} k g(x)} \eta_{J}(x) \mathrm{d} x . \tag{7}
\end{equation*}
$$

The result now follows from Lemma 1.4 applied to $\eta_{0}=f-I_{\Delta} f$.
Lemma 1.4. Let $G \subset \mathbb{C}$ be open and $g$, $\eta_{0}$ be holomorphic on $G$. Set $\gamma_{g}:=\left\|1 / g^{\prime}\right\|_{L^{\infty}(G)}$. For $\delta>0$ define $G_{\delta}:=\{z \in G \mid$ $\operatorname{dist}(z, \partial G)>\delta\}$. Starting from the function $\eta_{0}$, define the functions $\eta_{j}, j=1, \ldots$ recursively by (6). Then:

$$
\begin{equation*}
\left\|\eta_{j}\right\|_{L^{\infty}\left(G_{\delta}\right)} \leq\left(\frac{\gamma_{g} j}{\delta}\right)^{j}\left\|\eta_{0}\right\|_{L^{\infty}(G)}, \quad j=0,1, \ldots \tag{8}
\end{equation*}
$$

Here, we employ the convention $0^{0}=1$. If additionally $\eta^{(j)}\left(z_{0}\right)=0$ for $j=0, \ldots, p$ for a fixed $z_{0} \in G$, then $\eta_{j}\left(z_{0}\right)=0$ for $j=0, \ldots, p$.

Proof. We proceed by induction on $j$. The statement is true for $j=0$ by definition. Assuming it to be true for some $j \in \mathbb{N}_{0}$ and all $\delta>0$, we get for every $x \in G_{\delta}$ and every $0<\varepsilon<\delta$ by Cauchy's integral representation formula

$$
\begin{align*}
\left|\eta_{j+1}(x)\right| & =\left|\frac{1}{2 \pi \mathbf{i}} \int_{\partial B_{\varepsilon}(x)} \frac{\eta_{j}(t)}{g^{\prime}(t)(t-x)^{2}} \mathrm{~d} t\right| \leq \frac{1}{\varepsilon}\left\|1 / g^{\prime}\right\|_{L^{\infty}(G)}\left\|\eta_{j}\right\|_{L^{\infty}\left(G_{\delta-\varepsilon}\right)}  \tag{9}\\
& \leq \frac{\gamma_{g}}{\varepsilon}\left(\frac{\gamma_{g} j}{\delta-\varepsilon}\right)^{j}\left\|\eta_{0}\right\|_{L^{\infty}(G)} . \tag{10}
\end{align*}
$$

If $j=0$, we let $\varepsilon \rightarrow \delta$ in (9) to see that (8) is true for $j=1$. For $j \geq 1$, we select $\varepsilon:=\delta \frac{1}{j+1}<\delta$ to get from (10)

$$
\left|\eta_{j+1}(x)\right| \leq\left(\frac{\gamma_{g}(j+1)}{\delta}\right)^{j+1}\left\|\eta_{0}\right\|_{L^{\infty}(G)}
$$

Noting that $x \in G_{\delta}$ is arbitrary, we can conclude the induction step. Finally, if $\eta_{0}$ and its derivatives up to order $p$ vanish at $z_{0}$, then $\left\|\eta_{0}\right\|_{L^{\infty}\left(B_{r}\left(z_{0}\right)\right)} \leq C r^{p+1}$ for all sufficiently small $r>0$. Taking $G=B_{r}\left(z_{0}\right)$ and $\delta=r / 2$ and letting $r \rightarrow 0$, the bound (8) then implies $\eta_{j}\left(z_{0}\right)=0$ for $j=0, \ldots, p$.

### 1.2. Polynomial interpolation

The following result is classical in polynomial interpolation of holomorphic functions and can be found, for example, in [5, Chapter IV]:

Proposition 1.5 (Hermite). Let $f \in L^{\infty}(D(f))$ be holomorphic on the domain $D(f)$. Let $\Delta=\left(z_{0}, \ldots, z_{n}\right)$ and set $\omega_{\Delta}(z):=$ $\prod_{i=0}^{n}\left(z-z_{i}\right)$. Then for every $z \in D(f)$ and every simple, closed Jordan curve $\mathcal{C} \subset D(f)$ with $\left\{z, z_{0}, \ldots, z_{n}\right\} \in \operatorname{Int}(\mathbb{C}) \subset D(f)$ there holds

$$
\begin{equation*}
f(z)-I_{\Delta} f(z)=\frac{1}{2 \pi \mathbf{i}} \int_{t \in \mathcal{C}} \frac{\omega_{\Delta}(z)}{\omega_{\Delta}(t)} \frac{f(t)}{t-z} \mathrm{~d} t \tag{11}
\end{equation*}
$$

Furthermore, for every compact $K \subset D(f)$ there exist $C, \gamma>0$ depending solely on $K$ and $D(f)$ such that if $\Delta \subset K$ then

$$
\begin{equation*}
\left|f(z)-I_{\Delta} f(z)\right| \leq C\left|\omega_{\Delta}(z)\right| \gamma^{n+1}\|f\|_{L^{\infty}(D(f))} \quad \forall z \in K \tag{12}
\end{equation*}
$$

Proof. The representation (11) is taken from [5, Chapter IV]; to see (12), select a Jordan curve $\mathcal{C} \subset D(f)$ with $K \subset \operatorname{Int}(\mathcal{C})$. Then, $\operatorname{dist}(\mathcal{C}, \Delta) \geq \operatorname{dist}(\mathcal{C}, K)>0$. Hence, $\left|\omega_{\Delta}(t)\right| \geq C \operatorname{dist}(\mathcal{C}, K)^{n+1}$, and (12) follows from (11).

Of particular interest here is Hermite interpolation in the endpoints given by

$$
\begin{equation*}
\Delta_{H}^{2 p-1}:=(\underbrace{-1, \ldots,-1}_{p \text { times }}, \underbrace{1, \ldots, 1}_{p \text { times }}) . \tag{13}
\end{equation*}
$$

The Hermite interpolation operator $I_{\Delta_{H}^{2 p-1}}: C^{p-1}([-1,1]) \rightarrow \mathcal{P}_{2 p-1}$ is characterized by the conditions

$$
\begin{equation*}
f^{(j)}( \pm 1)=\left(I_{\Delta_{H}^{2 p-1}} f\right)^{(j)}( \pm 1), \quad j=0, \ldots, p-1 \tag{14}
\end{equation*}
$$

Lemma 1.6 will express the approximation properties of $I_{\Delta_{H}^{2 p-1}}$ in terms of the functions $\omega_{2 p}^{H}, \omega^{H}$, and the sets $W_{r}^{H}$ :

$$
\begin{align*}
& \omega_{2 p}^{H}(z)=(z+1)^{p}(z-1)^{p}=\left(z^{2}-1\right)^{p}, \quad \omega^{H}(z):=\left|z^{2}-1\right|^{1 / 2}  \tag{15}\\
& W_{r}^{H}=\left\{z \in \mathbb{C} \mid \omega^{H}(z)=\sqrt{\left|z^{2}-1\right|}<r\right\} \tag{16}
\end{align*}
$$

The sets $W_{r}^{H}$ are nested: $\operatorname{clo}\left(W_{r^{\prime}}^{H}\right) \subset W_{r}^{H}$ for $r^{\prime}<r$. We note that the interval $[-1,1]$ is only contained in the sets $W_{r}^{H}$ for $r>1$. Then, however, already the interval $[-\sqrt{2}, \sqrt{2}]$ is contained in $W_{r}^{H}$ (see Fig. 1). The error representation (11) gives us:

Lemma 1.6. Let $f$ be holomorphic on the domain $D(f)$, and let $r>1$ be such that $\operatorname{clo}\left(W_{r}^{H}\right) \subset D(f)$. Then for every $0<r^{\prime}<r$ there exists $C>0$ (depending only on $\left.r, r^{\prime}\right)$ such that for every $\delta$ with $B_{\delta}(\{ \pm 1\}) \subset W_{r^{\prime}}^{H}$ :

$$
\begin{aligned}
& \left\|f-I_{\Delta_{H}^{2 p-1}} f\right\|_{L^{\infty}\left(w_{r^{\prime}}^{H}\right)} \leq C\left(\frac{r^{\prime}}{r}\right)^{2 p}\|f\|_{L^{\infty}\left(W_{r}^{H}\right)} \quad \forall p \in \mathbb{N}_{0}, \\
& \left|\left(f-I_{\Delta_{H}^{2 p-1}} f\right)(z)\right| \leq C\left(\frac{\delta(2+\delta)}{r^{2}}\right)^{p}\|f\|_{L^{\infty}\left(W_{r}^{H}\right)} \quad \forall z \in B_{\delta}(\{ \pm 1\}) .
\end{aligned}
$$

Fig. 1. $\partial W_{r}^{H}$ (i.e., the level lines of $\omega^{H}(z)=\sqrt{\left|z^{2}-1\right|}$ ) for $r \in\{0.8,1,1.1,1.2\}$.
A perturbation argument allows us to infer from Lemma 1.6 error bounds for interpolation that clusters points near the endpoints:

Lemma 1.7. Let $1<r^{\prime}<r$ and $q \in\left(\left(r^{\prime} / r\right)^{2}\right.$, 1). Then there exist constants $\delta_{0}, C, \gamma>0$, which depend only on $r, r^{\prime}, q$, such that the following is true: For any $\delta \in\left(0, \delta_{0}\right]$ and $\Delta^{2 p-1}$ with $2 p$ points satisfying

$$
\begin{equation*}
\Delta^{2 p-1} \text { has exactly } p \text { points in } B_{\delta}(-1) \text { and exactly points } p \text { in } B_{\delta}(1) \tag{17}
\end{equation*}
$$

the interpolation error $f-I_{\Delta} f$ satisfies

$$
\begin{align*}
& \left\|f-I_{\Delta} f\right\|_{L^{\infty}\left(w_{r^{\prime}}^{H}\right)} \leq C q^{p}\|f\|_{L^{\infty}\left(w_{r}^{H}\right)},  \tag{18}\\
& \left|\left(f-I_{\Delta} f\right)(z)\right| \leq(\delta \gamma)^{p}\|f\|_{L^{\infty}\left(w_{r}^{H}\right)} \quad \forall z \in B_{\delta}(\{ \pm 1\}) . \tag{19}
\end{align*}
$$

Proof. Let $z_{i}, i=0, \ldots, p-1$ be the points of $\Delta^{2 p-1}$ in $B_{\delta}(-1)$ and let $\tilde{z}_{i}, i=0, \ldots, p-1$ be the points of $\Delta^{2 p-1}$ in $B_{\delta}(1)$. We then write for $z \neq \pm 1$ :

$$
\omega_{\Delta^{2 p-1}}(z)=\prod_{i=0}^{p-1}\left(z-z_{i}\right) \prod_{i=0}^{p-1}\left(z-\tilde{z}_{i}\right)=\left(z^{2}-1\right)^{p} \prod_{i=0}^{p-1}\left(1+\frac{-1-z_{i}}{z+1}\right) \prod_{i=0}^{p-1}\left(1+\frac{1-\tilde{z}_{i}}{z-1}\right) .
$$

Hence, we can find $\gamma>0$ depending only on $r, r^{\prime}$ such that for any $p \in \mathbb{N}_{0}$

$$
\begin{equation*}
(1-\gamma \delta)^{2 p}\left|\omega_{2 p}^{H}(z)\right| \leq\left|\omega_{\Delta^{2 p-1}}(z)\right| \leq(1+\gamma \delta)^{2 p}\left|\omega_{2 p}^{H}(z)\right| \quad \forall z \in W_{r}^{H} \backslash W_{r^{\prime}}^{H} \tag{20}
\end{equation*}
$$

Choosing $\delta$ sufficiently small, we can make $\left|\omega_{\Delta^{2 p-1}}(z) / \omega_{2 p}^{H}(z)\right|^{1 /(2 p)}$ arbitrarily close to 1 uniformly in $z \in W_{r}^{H} \backslash W_{r^{\prime}}^{H}$. By the maximum modulus principle for holomorphic functions (18) is shown once $\left|f(z)-I_{\triangle} f(z)\right|$ can be bounded by the right-hand side of (18) for $z \in \partial W_{r^{\prime}}^{H}$. However, this follows from (15), (20) and (11) with $\mathcal{C}=\partial W_{r}^{H}$. For (19), we insert into the error formula (11) the bound $\left|\omega_{\Delta^{2 p-1}}(z)\right| \leq(2 \delta)^{p}(2+2 \delta)^{p}$ together with (20) and (15).

## 2. Quadrature error analysis

## 2.1. k-asymptotics

Theorem 2.1 (k-asymptotics). Let Assumption 1.1 be valid and let $[-1,1] \subset K \subset g_{g}$ be compact. Set $\gamma_{g}:=\left\|1 / g^{\prime}\right\|_{L^{\infty}\left(g_{g}\right)}$. Fix $\delta_{0}<\min \left\{1, \operatorname{dist}\left(\{ \pm 1\}, \partial \mathcal{G}_{g}\right)\right\}$. Then there exist constants $C, \gamma>0$ that depend solely on $K$, $\operatorname{dist}\left(K, \partial \mathcal{G}_{g}\right)>0$, and $\delta_{0}$ such that for arbitrary interpolation points $\Delta=\left(z_{0}, \ldots, z_{n}\right)$ with $\Delta \subset K$ the following holds:
(i) Let $p \in \mathbb{N}_{0}$ be such that $\left(f-I_{\Delta} f\right)^{(j)}( \pm 1)=0$ for $0 \leq j \leq p-1$. Then

$$
\left|Q(f)-Q_{\Delta}(f)\right| \leq C \gamma^{n+1} \min \left\{1,\left(\frac{\gamma_{g}(p+1)}{|k|}\right)^{p+1}\right\}\|f\|_{L^{\infty}\left(g_{g}\right)} .
$$

(ii) For $\delta>0$ such that $\delta /|k| \leq \delta_{0}$ denote by $p_{-1, \delta}:=\operatorname{card}\left\{i \mid 0 \leq i \leq n, z_{i} \in B_{\delta /|k|}(-1)\right\}$ and $p_{1, \delta}:=\operatorname{card}\left\{i \mid 0 \leq i \leq n, z_{i} \in\right.$ $\left.B_{\delta /|k|}(1)\right\}$ the number of interpolation points in the $\delta /|k|$-neighborhoods of -1 and 1 , respectively. Set $p_{\delta}:=\min \left\{p_{-1, \delta}, p_{1, \delta}\right\}$. Then

$$
\left|Q(f)-Q_{\Delta}(f)\right| \leq C \gamma^{n+1} \frac{\gamma_{g}}{|k|} \min \left\{1,\left(\frac{\delta+\gamma_{g}\left(p_{\delta}+1\right)}{|k|}\right)^{p_{\delta}}\right\}\|f\|_{L^{\infty}(g g)}
$$

Proof. (5) together with (12) gives $\left|Q(f)-Q_{\Delta}(f)\right| \leq C \gamma^{n+1}\|f\|_{L^{\infty}\left(g_{g}\right)}$. To complete the proof of (i), we apply Lemma 1.3 with $J_{0}=p, J=p+1, \delta=d=1 / 2 \operatorname{dist}\left([-1,1], \partial \mathcal{G}_{g}\right)$ and again $(12)$ (with the compact set $\operatorname{clo}\left(B_{d}([-1,1])\right)$ ).

To see (ii), let $K^{\prime} \subset g_{g}$ be compact such that $B_{\delta_{0}}(\{ \pm 1\}) \cup B_{d}([-1,1]) \subset K^{\prime}$ for some $0<d<1 / 2$. (12) provides a constant (again denoted $\gamma$ ) such that for $z \in B_{\delta /|k|}(\{ \pm 1\})$ we have $\left|\left(f-I_{\Delta} f\right)(z)\right| \leq C(2 \delta /|k|)^{p_{\delta}} \gamma^{n+1}\|f\|_{L^{\infty}\left(g_{g}\right)}$ and $\left\|f-I_{\Delta} f\right\|_{L^{\infty}\left(K^{\prime}\right)} \leq C \gamma^{n+1}\|f\|_{L^{\infty}\left(g_{g}\right)}$. Lemma 1.3 with $J_{0}=0, J=1$ gives

$$
E:=\left|Q(f)-Q_{\Delta}(f)\right| \leq C \gamma^{n+1} \frac{\gamma_{g}}{|k|}\|f\|_{L^{\infty}\left(g_{g}\right)}
$$

This is the first bound. Lemma 1.3 with $J_{0}=0$ and $J=p_{\delta}+1$ gives

$$
\begin{aligned}
E & \leq C \gamma^{n+1}\|f\|_{L^{\infty}\left(g_{g}\right)}\left[\frac{\gamma_{g}}{|k|} \sum_{j=0}^{p_{\delta}}|k|^{-j}\left(\frac{\gamma_{g} j}{\delta /|k|}\right)^{j}\left(\frac{2 \delta}{|k|}\right)^{p_{\delta}}+\left(\frac{\left(p_{\delta}+1\right) \gamma_{g}}{d|k|}\right)^{p_{\delta}+1}\right] \\
& \leq C \gamma^{n+1} \frac{\gamma_{g}}{|k|}\left(\frac{\gamma_{g}}{|k|}\right)^{p_{\delta}}\|f\|_{L^{\infty}\left(g_{g}\right)}\left(\sum_{j=0}^{p_{\delta}}\left(\frac{\gamma_{g} j}{\delta}\right)^{j}\left(\frac{2 \delta}{\gamma_{g}}\right)^{p_{\delta}}+\left(\frac{p_{\delta}+1}{d}\right)^{p_{\delta}+1}\right) .
\end{aligned}
$$

The convexity of the function $j \mapsto\left(j \gamma_{g} / \delta\right)^{j}\left(2 \delta / \gamma_{g}\right)^{p_{\delta}}$ then gives us

$$
\begin{aligned}
E & \leq C \gamma^{n+1} \frac{\gamma_{g}}{|k|}\left(\frac{\gamma_{g}}{|k|}\right)^{p_{\delta}}\|f\|_{L^{\infty}\left(g_{g}\right)} \times\left(\left(p_{\delta}+1\right) \max \left\{\left(\frac{2 \delta}{\gamma_{g}}\right)^{p_{\delta}},\left(2 p_{\delta}\right)^{p_{\delta}}\right\}+\left(\frac{p_{\delta}+1}{d}\right)^{p_{\delta}+1}\right) \\
& \leq C \gamma^{n+1}\left(p_{\delta}+1\right) \frac{\gamma_{g}}{|k|}\left(\frac{\gamma_{g}}{|k|}\right)^{p_{\delta}}\|f\|_{L^{\infty}\left(g_{g}\right)}\left(\max \left\{\frac{2 \delta}{\gamma_{g}}, \frac{p_{\delta}+1}{d}, 2 p_{\delta}\right\}\right)^{p_{\delta}} .
\end{aligned}
$$

Noting $p_{\delta} \leq n+1$ and adjusting the constant $\gamma$ gives the desired bound.

### 2.2. Convergent Filon quadrature

As Theorem 2.1 shows, it is advantageous to cluster interpolation points near the endpoints $\pm 1$ for large $|k|$. Convergence (as $n \rightarrow \infty$ ) of Filon quadrature that is based on such interpolation point distribution can only be expected under suitable conditions on the size of the domain of analyticity of $f$. The following theorem shows that in the case of pure Filon quadrature the domain of analyticity $\mathcal{G}_{f}$ of $f$ should contain $W_{1}^{H}$ :

Theorem 2.2 (Pure Filon Quadrature). Let $\Delta_{H}^{2 p-1}$ be given by (13). Let Assumption 1.2 be valid. Set $\gamma_{g}:=\left\|1 / g^{\prime}\right\|_{L^{\infty}\left(g_{g}\right)}$. Then there exist $C, \gamma>0$ (depending only on $r$ and $\left.\operatorname{dist}\left([-1,1], \partial \mathscr{q}_{g}\right)\right)$ such that

$$
\left|Q(f)-Q_{\Delta_{H}^{2 p-1}}(f)\right| \leq C\left(\min \left\{r^{-2}, \gamma \frac{\gamma_{g}(p+1)}{|k|}\right\}\right)^{p+1}\|f\|_{L^{\infty}\left(W_{r}^{H}\right)}
$$

Proof. (5) and Lemma 1.6 with $r^{\prime}=1$ (note: $[-1,1] \subset \operatorname{clo}\left(W_{1}^{H}\right)$ ) give the error bound $\left|Q(f)-Q_{\Delta_{H}^{2 p-1}}(f)\right| \leq C r^{-2 p}\|f\|_{L^{\infty}\left(W_{r}^{H}\right)}$. Adjusting the constant by the factor $r^{2}$ gives the first estimate. For the second one, select $0<d \leq \operatorname{dist}\left([-1,1], \partial g_{g}\right)$ such that $B_{d}([-1,1]) \subset W_{r^{\prime}}^{H}$ for some $r^{\prime}<r\left(\right.$ e.g., $\left.r^{\prime}=(1+r) / 2\right)$ and apply Lemma 1.6 to Lemma 1.3 with $J_{0}=p, J=p+1$.

### 2.3. Derivative-free Filon quadrature

Quadrature formulas that avoid knowledge of derivatives are of interest. [1] proposes to cluster the interpolation points near the endpoints $\pm 1$. As in the case of the pure Filon quadrature, Assumption 1.2 is the key to ensure convergence as $n \rightarrow \infty$ :

Theorem 2.3. Let Assumption 1.2 be valid. Fix $q \in\left(1 / r^{2}, 1\right)$. Set $\gamma_{g}:=\left\|1 / g^{\prime}\right\|_{L^{\infty}\left(g_{g}\right)}$. Then there exist $\delta_{0}, C, \gamma>0$ (all depending only on $r, q$, $\left.\operatorname{dist}\left([-1,1], \partial \mathcal{G}_{g}\right)\right)$ such that for any $\delta$ with $\delta /|k| \leq \delta_{0}$ and any $\Delta^{2 p-1}$ satisfying
$\Delta^{2 p-1}$ has exactly p points in $B_{\delta /|k|}(-1)$ and exactly $p$ points in $B_{\delta /|k|}(1)$
the corresponding Filon quadrature $Q_{\Delta^{2 p-1}}$ satisfies

$$
\left|Q(f)-Q_{\Delta^{2 p-1}}(f)\right| \leq C \frac{\gamma_{g}}{|k|} \min \left\{q, \gamma \frac{\delta+\gamma_{g}(p+1)}{|k|}\right\}^{p}\|f\|_{L^{\infty}\left(w_{r}^{H}\right)}
$$

Proof. The proof follows from the arguments given in the proof of Theorem 2.1 and an appeal to Lemma 1.7.
The following point distribution guarantees a smooth transition from an extreme clustering near the endpoints $\pm 1$ to the asymptotic distribution that essentially coincides with the Chebyshev points:

$$
\begin{align*}
& \Delta_{C}^{2 p-1}:=\left(z_{0}, \ldots, z_{p-1},-z_{p-1},-z_{p-2}, \ldots,-z_{0}\right)  \tag{22a}\\
& z_{i}=\cos \theta_{i}, \quad \theta_{i}:=i \delta_{C}, \quad \delta_{C}:=\frac{\pi}{2} \min \left\{\frac{\lambda}{|k|}, \frac{1}{p-1 / 2}\right\} \tag{22b}
\end{align*}
$$

here $\lambda>0$ is a user-chosen parameter. The Filon quadrature based on $\Delta_{C}^{2 p-1}$ converges under the same conditions on $f$ and $g$ as the pure Filon quadrature:

Theorem 2.4. Let Assumption 1.2 be valid. Then there exist $q \in(0,1), C, \gamma>0$, and an open neighborhood $U$ of $[-1,1]$ (depending only on $r$ and $\operatorname{dist}\left([-1,1], \partial g_{g}\right)$ ) such that $f-I_{\Delta_{C}^{2 p-1}} f$ with $\Delta_{C}^{2 p-1}$ given by (22) satisfies

$$
\begin{equation*}
\left\|f-I_{\Delta_{C}^{2 p-1}} f\right\|_{L^{\infty}(u)} \leq C q^{p}\|f\|_{L^{\infty}\left(W_{r}^{H}\right)} \quad \forall p \in \mathbb{N}_{0} . \tag{23}
\end{equation*}
$$

Upon setting $\gamma_{g}:=\left\|1 / g^{\prime}\right\|_{L^{\infty}\left(g_{g}\right)}$, the Filon quadrature based on $\Delta_{C}^{2 p-1}$ satisfies

$$
\begin{equation*}
\left|Q(f)-Q_{\Delta_{C}^{2 p-1}}(f)\right| \leq C \frac{\gamma_{g}}{|k|} \min \left\{q, \gamma \frac{\delta_{C} p|k|+\gamma_{g}(p+1)}{|k|}\right\}^{p}\|f\|_{L^{\infty}\left(g_{f}\right)} \tag{24}
\end{equation*}
$$

Proof. See [6]. The result shows that the parameter $\lambda$ should be chosen proportional to $\gamma_{g}$. The constants $C, q, \gamma$ are independent of $\lambda$.

## 3. Integrands with small domain of analyticity

Theorem 2.2 shows that the pure Filon quadrature converges as $n \rightarrow \infty$ provided the domain of analyticity $\mathscr{G}_{f}$ is sufficiently large-the numerical experiments in Section 4 indicate sharpness of the result. Theorem 2.4 shows that convergent derivative-free quadrature rules can be devised under the same regularity assumptions. As pointed out above, the condition $[-1,1] \subset W_{r}^{H}$ is only satisfied for $r>1$, in which case already $[-\sqrt{2}, \sqrt{2}] \subset W_{r}^{H}$. Thus, the domain of analyticity of $f$ and $g$ cannot be an arbitrary open neighborhood of $[-1,1]$. We now discuss two options to create convergent Filon-type quadrature for integrands $f$ whose domain of analyticity is just an open neighborhood of $[-1,1]$ : In Section 3.1, we present composite Filon-type quadratures, and in Section 3.2 we insert additional quadrature points in the interval $[-1,1]$.

### 3.1. Composite Filon-type quadratures

Assumption 3.1. $Q_{k, p}^{\text {ref }}(f, g)$ is a quadrature rule for integration on $[-1,1]$ with the following property: For every $f, g$ satisfying Assumption 1.2 there exist constants $C, \gamma>0, q \in(0,1)$ (all depending only on $r>1$ and dist $\left([-1,1], \partial \mathcal{g}_{g}\right)$ ) such that, upon setting $\gamma_{g}:=\left\|1 / g^{\prime}\right\|_{L^{\infty}\left(g_{g}\right)}$, there holds

$$
\begin{equation*}
\left|Q(f)-Q_{k, p}^{\mathrm{ref}}(f, g)\right| \leq C \min \left\{q, \gamma \frac{\gamma_{g}(p+1)}{|k|}\right\}^{p+1}\|f\|_{L^{\infty}\left(g_{f}\right)} \quad \forall p \in \mathbb{N}_{0} \tag{25}
\end{equation*}
$$

Assumption 3.1 is satisfied in the settings of Theorems 2.2 and 2.4 (if the parameter $\lambda$ is chosen proportional to $\gamma_{g}$ ). A composite quadrature rule is obtained in the usual way: For a partition $\mathcal{T}$ of $[-1,1]$ into elements $K$ of size $h_{K}$ and affine bijections $F_{K}:[-1,1] \rightarrow K$ the composite quadrature rule $Q_{\tau, k, p}$ is defined as

$$
Q_{\mathcal{T}, k, p}(f, g):=\sum_{K \in \mathcal{T}} \frac{h_{K}}{2} Q_{k, p}^{\mathrm{ref}}\left(\left.f\right|_{K} \circ F_{K},\left.g\right|_{K} \circ F_{K}\right)
$$

Theorem 3.2. Let $Q_{k, p}^{\text {ref }}$ satisfy Assumption 3.1. Let $f, g$ satisfy Assumption 1.1. Set $\gamma_{g}:=\left\|1 / g^{\prime}\right\|_{L^{\infty}\left(g_{g}\right)}$. Assume that $\mathcal{T}$ satisfies, for some $r>1$,

$$
\begin{equation*}
F_{K}^{-1}\left(g_{f}\right) \supset W_{r}^{H} \quad \forall K \in \mathcal{T} \tag{26}
\end{equation*}
$$

Then, there exist constant $C, \gamma>0$ depending only on the constants appearing in Assumption 3.1 and dist $\left([-1,1], \partial g_{g}\right)$ such that

$$
\begin{equation*}
\left|Q(f)-Q_{\mathcal{T}, k, p}(f, g)\right| \leq C \sum_{K \in \mathcal{T}} h_{K} \min \left\{q, \gamma \frac{\gamma_{g}(p+1)}{h_{K}|k|}\right\}^{p+1}\|f\|_{L^{\infty}\left(g_{f}\right)} \tag{27}
\end{equation*}
$$

Proof. We observe that $\left(\left.g\right|_{K} \circ F_{K}\right)^{\prime}=\frac{h_{K}}{2} g^{\prime} \circ F_{K}$. Hence, the constant $\gamma_{g}$ appearing in (25) is adjusted by a factor $2 / h_{K}$, which gives the claim.
Geometric considerations give an easy sufficient condition for (26) to be met: Denoting $m_{K} \in K$ the mid point of the element $K$, then (26) is fulfilled if

$$
\begin{equation*}
\operatorname{clo}\left(B_{\frac{\sqrt{2}}{2} h_{K}}\left(m_{K}\right)\right) \subset \mathcal{G}_{f} \quad \forall K \in \mathcal{T} \tag{28}
\end{equation*}
$$

### 3.2. Stabilized Filon-type quadratures

The composite quadrature that satisfies (26) can be viewed as inserting additional quadrature points in the interior of the integration domain. A similar effect can be achieved by combining Hermite interpolation with interpolation in, for example, the Gauß points. To fix ideas, denote by $\Delta_{G}^{n}$ the $n+1$ Gauß points and define, for a parameter $m \in \mathbb{N}_{0}$ to be chosen, the stabilized rule with points $\Delta_{S}^{m p+2 p}:=\Delta_{G}^{m p} \cup \Delta_{H}^{2 p-1}$. That is, we use $m p+2 p+1$ evaluations of $f$ or its derivatives in the quadrature. The quadrature error then satisfies:

Theorem 3.3 (Stabilized Filon-type Quadrature). Let Assumption 1.1 be valid. Set $\gamma_{g}:=\left\|1 / g^{\prime}\right\|_{L^{\infty}\left(g_{g}\right)}$. Then there exist constants $C, \gamma>0, q \in(0,1)$, and $m \in \mathbb{N}_{0}$ depending only on $\mathcal{G}_{f}$ and $\mathcal{G}_{g}$ such that

$$
\left|Q(f)-Q_{\Delta_{S}^{m p+2 p}}(f)\right| \leq C\left(\min \left\{q, \gamma \frac{\gamma_{g}(p+1)}{|k|}\right\}\right)^{p+1}\|f\|_{L^{\infty}\left(\mathscr{g}_{f}\right)}
$$

We note that the number of evaluations of $f$ and its derivatives is $(2+m) p+1$.
Proof. Proceed as in the proof of Theorem 2.2. The key observation is that the asymptotic distribution of the Gauß points is known, [5, Theorem 12.4.5]. Specifically, for the Gauß points $z_{i}^{(n)}, i=0, \ldots, n$ and $\omega_{n+1}^{G}(z):=\prod_{i=0}^{n}\left(z-z_{i}^{(n)}\right)$ we have $\lim _{n \rightarrow \infty}\left|\omega_{n+1}^{G}(z)\right|^{1 /(n+1)}=\frac{1}{2} \rho(z)$; here, $\rho(z)>1$ is determined by the condition $z \in \partial \varepsilon_{\rho(z)}$, where the ellipse $\varepsilon_{\rho}$ is given by $\varepsilon_{\rho}=\left\{z \in \mathbb{C}| | z-1|+|z+1|=\rho+1 / \rho\}\right.$. For $\omega_{\Delta_{S}^{(m+2) p}}(z):=\omega_{2 p}^{H}(z) \omega_{m p+1}^{G}(z)$ we compute

$$
\begin{equation*}
\omega_{m}^{S}(z):=\lim _{p \rightarrow \infty}\left|\omega_{\Delta_{S}^{(m+2) p}}(z)\right|^{1 /(2 p+m p+1)}=\left(\omega^{H}(z)\right)^{2 /(m+2)}\left(\frac{1}{2} \rho(z)\right)^{m /(m+2)} \tag{29}
\end{equation*}
$$

The representation $\rho(z)=\zeta+\sqrt{\zeta^{2}-1}$ where $2 \zeta=|z-1|+|z+1|$ shows that $\omega_{m}^{S}$ is a continuous function. Thus, the sets $W_{r}^{S}:=\left\{z \in \mathbb{C} \mid \omega_{m}^{S}(z)<r\right\}$ are open. Note $[-1,1] \subset W_{r}^{S}$ for $r>2^{-m /(m+2)}$. Fix $1<\rho$ such that $\operatorname{clo}\left(\varepsilon_{\rho}\right) \subset D(f)$. Fix $1 / 2<r<\rho / 2$ and note that $\varepsilon_{\rho^{\prime}} \subset \varepsilon_{\rho}$ for $\rho^{\prime}<\rho$. Then (29) implies that for $m$ sufficiently large, we have $[-1,1] \subset W_{r}^{S} \subset \varepsilon_{\rho} \subset D(f)$. The approximation properties of the interpolation operator $I_{\Delta_{S}^{(2+m) p}}$ now follow from Proposition 1.5. Noting $\left(f-I_{\Delta_{s}^{(2+m) p}} f\right)^{(j)}( \pm 1)=0$ for $0 \leq j \leq p-1$ allows us to complete the proof by arguing as in the proof of Theorem 2.2.

Remark 3.4. Analogous results hold for Gauß-Lobatto or Chebyshev points.

## 4. Numerical examples

All calculations in this section are done in Maple using a sufficient number of digits to be able to focus on the convergence properties of the Filon quadrature. In the Examples 4.1-4.3 we consider

$$
\begin{equation*}
g(x)=1, \quad f_{1}(x)=\left(a-x^{2}\right)^{1 / 2}=(\sqrt{a}+x)^{1 / 2}(\sqrt{a}-x)^{1 / 2}, \quad a>1 \tag{30}
\end{equation*}
$$

Fig. 2. Top row and bottom left: pure Filon quadrature based on $\Delta_{H}^{2 p-1}$ for $a=1.5, a=2$, and $a=3$. Bottom right: composite Filon quadrature with geometric mesh (31) for $L=4, \sigma=0.2, a=1.01$.

Fig. 3. Filon quadrature based on $\Delta_{C}^{2 p-1}$ of (22) for $a=1.01$ (left), $a=3$ (right).

Example 4.1 (Pure Filon Quadrature Based on $\Delta_{H}^{2 p-1}$ ). Assumption 1.2 is only satisfied for $a>2$. For the pure Filon quadrature, we therefore expect convergence (as $p \rightarrow \infty$ ) only for $a>2$. In this case, we expect the initial convergence to be the more rapid the larger $|k|$ is. This is indeed visible in Fig. 2. For $a<2$ Theorem 2.1 suggests, for a problem-dependent constant $\gamma$, rapid error decay for $p \leq \gamma|k|$ and error increase for $p>\gamma|k|$. This behavior is also visible in Fig. 2 for the case $a=1.5$.

Fig. 4. Stabilized Filon quadrature based on $\Delta_{S C}^{m p+2 p}$ for $a=1.7$. Top row and bottom left: $m=0, m=1, m=2$. Bottom right: $k=100$ and $m \in\{0,1$, 2$\}$.

Example 4.2 (Filon Quadrature Based on $\Delta_{C}^{2 p-1}$ ). Theorem 2.4 ensures uniform (in $k$ ) convergence of the method $Q_{\Delta_{C}}^{2 p-1}$ for $a>2$. This is visible in Fig. 3 for the case $a=3$. For $a<2$, Theorem 2.4 leads us to expect good results for $k$ large compared to $p$ and, since for $p \geq|k| / \lambda$ the points essentially coincide with the classical Chebyshev points, also good results in that regime. In the intermediate regime, the estimates of Theorem 2.4 permit large errors; indeed, these arise as shown in Fig. 3 for the case $a=1.01$. The parameter $\lambda$ appearing in (22) is chosen as $\lambda=1$.

Example 4.3 (Composite Pure Filon Quadrature). Section 3.1 shows that composite Filon rules can make Filon quadrature applicable to integrands with singularities near the domain of integration. The condition to be satisfied is (26), or, more simply, (28). It is desirable to minimize the number of elements in the mesh $\mathcal{T}$ under the constraint (26). For the integrand given by (30), this can be achieved with geometric meshes that are refined towards the singularities of $f$ : Let the mesh $\mathcal{T}^{\text {geo }}$ be defined by the points

$$
\begin{equation*}
\left\{-1,-1+\sigma^{i}, \mid i=0, \ldots, L\right\} \cup\left\{1,1-\sigma^{i} \mid i=1, \ldots, L\right\} . \tag{31}
\end{equation*}
$$

If $\sigma>(\sqrt{2}-1)^{2}$, then - with the exception of the elements $K$ abutting the endpoints $\pm 1$ - condition (26) is satisfied by all $K \in \mathcal{T}$ regardless of $a>1$. Condition (26) is satisfied by the boundary elements only if $L$ is sufficiently small. Sufficiently conditions for $\mathcal{T}^{\text {geo }}$ to perform well are therefore:

$$
\sigma>(\sqrt{2}-1)^{2}, \quad L \geq L_{0} \quad \text { with } \frac{\sqrt{2}}{2} \sigma^{L_{0}}<\sqrt{a}-1=\operatorname{dist}([-1,1], \partial D(f))
$$

The numerical example shown in the bottom right part of Fig. 2 is done with $a=1.01, \sigma=0.2$, and $L=4$ and a pure Filon quadrature on each element. Since we show relative errors, we mention that $Q(f) \approx 1.4$ for $k=1, Q(f) \approx 0.01$ for $k=10$, $Q(f) \approx-0.0025$ for $k=100$.

Fig. 5. Left: composite pure Filon quadrature based on 2 elements of equal length, $a=1.7$. Right: stabilized Filon quadrature based on $\Delta_{S C}^{m p+2 p}$ with $a=4$, $m=1$.

Example 4.4 (Stabilized Filon Quadrature). We consider the case

$$
\begin{equation*}
g(x)=1, \quad f_{2}(x)=(\sqrt{a}+x)^{1 / 2}, \quad a>1 . \tag{32}
\end{equation*}
$$

We employ the stabilized Filon quadrature $\Delta_{S C}^{m p+2 p}$ based on Hermite interpolation in the endpoints and in the Chebyshev points:

$$
\begin{equation*}
\Delta_{S C}^{m p+2 p}:=\Delta_{H}^{2 p-1} \cup\left\{\left.\cos \left(\frac{2 i+1}{m p+1} \frac{\pi}{2}\right) \right\rvert\, i=0, \ldots, m p\right\} \tag{33}
\end{equation*}
$$

Assumption 1.2 is only satisfied for $a>2$. Hence, convergence (as $p \rightarrow \infty$ ) cannot be guaranteed for $a=1.7$ and $m=0$; indeed Fig. 4 suggests divergence as $p \rightarrow \infty$ for $m=0$. Convergence is ensured by selecting $m \geq 1$, which is visible in Fig. 4.

The error bound of Theorem 3.3 is of the form $u(p):=(\min \{q, \gamma(p+1) /|k|\})^{p+1}$ for some $q \in(0,1)$ and $\gamma>0$. For $q$ close to 1 the function $u$ is decreasing on $\left(0, \frac{|k|}{e \gamma}\right)$, increasing on $\left(\frac{|k|}{e \gamma}, \frac{q|k|}{\gamma}\right)$ and decreasing on $\left(\frac{q|k|}{\gamma}, \infty\right)$. Qualitatively, such a behavior is visible in Fig. 4 for the case $a=1.7$ and $m=1$. It is worth noting that the range of $p$ in which this undesirable behavior occurs is proportional to $|k|$. For sufficiently small $q$ the function $u$ is monotone. Indeed, the numerical experiment in the right part of Fig. 5 with $a=4$ and $m=1$ shows a better behavior.
