Giant pseudoaneurysm at the proximal vein graft anastomosis after Bentall procedure for Takayasu arteritis

Kenichi Hashizume, MD, Ryuichi Takahashi, MD, and Kouji Tsutsumi, MD

A 39-year-old man with Takayasu arteritis underwent a modified Bentall procedure with a 28-mm Hemashield tube graft (Hemashield Gold; Boston Scientific, Wayne, NJ) and an ATS standard 25-mm valve (ATS Medical, Inc, Minneapolis, Minn) with additional aortocoronary bypass surgery 4 years ago because of suspected ischemia of the left anterior descending artery during weaning from cardiopulmonary bypass.

The patient recently experienced pectoralgia, and subsequent multidetector computed tomography revealed a rare anastomotic pseudoaneurysm that had formed gradually (Figure 1). This appeared as a giant pseudoaneurysm 70 × 35 mm in diameter at the site of the saphenous vein bypass graft in front of the ascending aorta that had been replaced with the prosthetic graft. However, it was unclear whether the pseudoaneurysm was a proximal composite graft anastomosis or a coronary ostium anastomosis. There was no significant stenosis in the left anterior descending artery.

A corrective surgical procedure was performed through re-do median sternotomy after femorofemoral bypass because computed tomography confirmed that the pseudoaneurysm was not just under the sternum (Figure 2). Oftentimes, such aneurysms are large enough to abut the posterior table of the sternum. In this case, one option was to place the patient under profound hypothermic circulatory arrest before sternotomy. Another option was to clamp the aorta, because it was understood that the pseudoaneurysm consisted of the coronary ostium anastomosis.

When the pseudoaneurysm was opened after the distal end of the composite graft was clamped and cardioplegia was given antegrade from the pseudoaneurysm, the proximal end of the vein graft was found to have detached completely from the artificial aorta (Figure 3). To repair the pseudoaneurysm, we ligated the saphenous vein graft, which had been occluded, and closed the opening of the anastomosis of the vascular prosthesis.

We did not use profound hypothermia but approached the aneurysm with femorofemoral bypass and cardioplegic arrest alone in a less invasive manner. The patient’s postoperative course was uneventful.
