Abstract

This study aimed to research the preparation techniques of total flavones from loquat flower (TFLF), its anti-oxidation capacity, and its protective effect on hepatic injury. The best extraction parameters by orthogonal experimentation were water at 100°C, extraction time 2.5 hours, solid/liquid ratio 1:20, and three decoctions. The chromogenic reaction to the flavones showed that loquat flowers mainly contained flavone, flavonol, and flavanone compounds combining ortho-phenolic hydroxyl group structure in the 30% ethanol fraction. The anti-oxidant capacity of O2·− was 26.09% and of OH· was 83.01% by salicylic acid and pyrogallol auto-oxidation. Compared with the model group, TFLF lowered the levels of alanine aminotransferase, aspartate aminotransferase, triglyceride, and malondialdehyde and liver index significantly, and upregulated the expression of adipose triglyceride lipase and Heine oxygense-1 mRNA. The present findings suggest that TFLF has protective effect on acute alcoholinduced liver injury in mice and may be related to its antioxidant and free-radical scavenging activity.

1. Introduction

Loquat flower is the dry flower of Eriobotrya japonica (Thunb.) Lindl, which belongs to Eriobotrya, Rosaceae. In traditional Chinese medicine, loquat flower is tasteless, tepid, into the lung meridian. Loquat flower has been mainly used to treat common cold, cough, rhinorrhea with clear discharge, immune deficiency, phlegm with blood, and so on. In the countryside, it is commonly used for children who cough with lung heat and patients with persistent cough [1]. China is abundant
2. Materials and methods

2.1. Plant material

Loquat flowers, which were provided by Shanghai Lian-Yi Loquat Ecological Park, were authenticated to be the dry alabastrom of white loquat belonging to Eriobotrya of Rosaceae by Professor Hui-ming Wang, Department of Pharmacognosy, Zhejiang Chinese Medical University, China.

2.2. Animals

Animals used in this study were male Kun Ming mice, weighing 19 ± 1 g provided by the Department of Laboratory Animal Science, Medical Center of Fudan University, Shanghai, China. Animals were fed in a standard animal house at an ambient temperature of 22 ± 2°C and 40–60% relative humidity. Animals were allowed free access to food and water.

2.3. Chemicals

DM301 macroporous adsorptive resin was purchased from Cangzhou Baoen Adsorbing Material Technology (10 Beihai road, Cangzhou, China). Bifendate Pills was purchased from Zhejiang medicine corporation (268 Dengyun road, Hangzhou, China). Triglyceride (TG), alanine aminotransferase (ALT), aspartate amino transferase (AST), and malondialdehyde (MDA) kits were purchased from Nanjing Jiancheng Bioengineering Institute (258-27 Central road, Nanjing, China). All other chemicals used were of analytical grade.

2.4. Determination of the content of total flavonoids

The content of total flavonoids in loquat flowers (TFLF) was detected using the Al(NO₃)₃–NaNO₂–NaOH colorimetric method [6]. Briefly, rutin was used as standard substance, and was dissolved in methanol to get a concentration of 1 mg/mL. The solution was diluted with distilled water to get the 0.05 mg/mL rutin standard solution. Aliquots of 0.0 mL, 0.4 mL, 0.8 mL, 1.6 mL, 2.4 mL, 3.2 mL, and 4.0 mL of the rutin standard solution were diluted with distilled water to 4.0 mL, and 0.2 mL of 5% NaNO₃ was added. After 6 minutes, 0.2 mL of 10% Al(NO₃)₃ was added, and then 1.6 mL of 4% NaOH was added and mixed. The absorbance value was measured at 510 nm after 15 minutes. The standard curve was drawn with the abscissa of rutin concentration (0–0.05 mg/mL), and the ordinate of absorbance value. The regression equation was $A = 0.0068C + 0.0017$, $R^2 = 0.9999$. The concentration of rutin (C) and absorbance (A) were in good linear relationship within 0.00–0.05 mg/mL (Fig. 1). Flavonoids content was determined according to the above method.

2.5. Extraction of TFLF

TFLF was extracted according to the procedure of traditional boiling optimized by orthogonal experiment, and macroporous resin chromatography.

The optimal conditions of solid–liquid ratio, extraction temperature, and decocting time were investigated through single factor tests. According to the results of single factor experiments, the identified optimum extracting procedure was optimized with L₉(3⁴) orthogonal experiment. A 60 g sample of crude total flavonoids extracted from loquat flowers using optimal methods was dissolved with distilled water, and loaded on to the DM301 macroporous adsorption resin column (6 cm × 50 cm) at the flow rate of 15 mL/min. Ethanol at 0% (water), 10%, 30%, 50% was used to elute the column at 25 mL/min. Each fraction of 200 mL was collected and the total volume of stepwise elution was 4000 mL; the concentration of flavonoids in each fraction was detected, then the concentration of fraction above 80% was collected, and named as TFLF.

2.6. Components analysis of TFLF

2.6.1. HCl–Zn reaction

A 1-mL aliquot of 10% sample ethanol solution and 30 mg Zn dust were added into a test tube and mixed; 100 mL of 10M HCl was added and the color change of the solution observed for several minutes. Most flavone, flavonol, flavanone, and flavanool compounds will become red to prunosus, and some...
will become blue or green. The color will become deeper, especially when the benzene ring is replaced by auxochrome. Meanwhile the same sample without Zn dust but with 100 μL of 10M HCl was taken as the blank control to avoid the false positive reactions. If the solution becomes red, this indicates that the sample contains pigments or some aurones or flavonol or chalcone.

2.6.2. KBH₄ reduction reaction
A 100-μL aliquot of 10% sample ethanol solution was dropped on a silica gel plate, sprayed with 1% KBH₄-isopropanol solution, and fumigated with 10M HCl after 5 minutes. Flavonone and flavanonol were reduced to become red to prunosus. The color will be deeper if A and B annulations are substituted by chalcone. The other flavones give a negative reaction.

2.6.3. AlCl₃ reaction
A 100-μL aliquot of 10% sample ethanol solution was dropped on a filter paper, then 2% AlCl₃ ethanol solution was sprayed and observed in UV light. If yellow fluorescence is observed, this suggests that it contains 5-OH flavonoids. If blue sky fluorescence is observed, this demonstrates that it contains 4’-OH flavonol or 7,4’-OH flavonol compounds.

2.6.4. FeCl₃ reaction
A 100-μL aliquot of FeCl₃ solution was added to 2 mL of 10% sample ethanol solution. A positive chromogenic reaction showed the existence of phenol hydroxyl.

2.6.5. SrCl₂ reaction
A 2-mL aliquot of 10% sample ethanol solution was taken into a test tube; 100 μL of 0.01 mM SrCl₂ methanol solution and 100 μL of methanol solution saturated by ammonia vapor were added. If any green to brown or even black precipitation is generated, this suggests that adjacent two phenolic hydroxyl groups are present.

2.6.6. PbAc₂ reaction
A 1 mL aliquot of 10% sample solution was taken into a test tube, then 1 mL of 1% PbAc₂ aqueous solution in distilled water was added; its color change and the presence of precipitation after shaking was observed. A positive reaction denoted that the sample contained an ortho-diphenolic hydroxyl group or combined with 3-OH, 4-ketone group or 5-OH,4-ketone group of the structure.

2.6.7. Na₂CO₃ reaction
A 1 mL aliquot of 10% sample solution was taken into a test tube and 1 mL 1% Na₂CO₃ solution added. Its color change and the presence of precipitation after shaking were observed, with a positive reaction indicating that the sample contained flavonol compounds [7].

2.7. Detection of antioxidant capacity of TFLF

2.7.1. Clearance test of superoxide radical anion
The test was carried out using the method of Wang et al [8] with some modifications. Briefly, 0.05M Tris-HCl (pH 8.2) and 10 mM pyrogallol were preheated at 25°C for 20 minutes; 2 mL 0.05M Tris-HCl buffer was mixed with 100 μL distilled water and 50 μL 10mM pyrogallol. Tris-HCl buffer (0.05M) was used as zero setting, with absorbance (A₀) measured at 325 nm/30 seconds. The linear regression was done with absorbance (Aₚ) and ordinate A (absorbance), and the slope was recorded as V₀. Then another 2 mL 0.05M Tris-HCl buffer was taken and the distilled water replaced with 100 μL 2 mg/mL TFLF and 2 mL VC (positive control) to determine the absorbance (A₁) with the same methods. Its slope was V₁. The capacity of superoxide radical anion clearance was calculated with the following formula:

\[
\text{Clearance rate} \% = \frac{(V₀ - V₁)}{V₀} \times 100\%
\]  

2.7.2. Clearance test of hydroxyl radical

The test was carried out according to the Fenton reaction by the procedures of Luo et al [9] with some modifications. Briefly, 2 mL 2 mg/mL TFLF, 1 mL 9 mM salicylic acid—ethanol solution, 1 mL 9mM FeSO₄, and 8.8mM H₂O₂ were added into a test tube with 37°C water heating for 30 minutes. Then the absorbance (Aₚ) at 510 nm was measured with double distilled water used as zero setting. Meanwhile, the absorbance (A₀) was determined with 2 mg/mL of VC as the positive control and equal-volume distilled water as the blank control. Because the TFLF itself had a little absorbance, H₂O₂ was replaced by an equal volume of distilled water as the blank control to determine the absorbance (A₂). The clearance capacity was calculated using the following formula:

\[
\text{Clearance} = \frac{|A₀ - (A₁ - A₂)|}{A₀} \times 100\%
\]  

2.8. Detection of protective effect of TFLF on acute alcohol-induced liver injury in mice

2.8.1. Animal treatment and biochemical analysis
Fifty-six male Kunming mice were randomly assigned to seven groups of eight mice each: control group; model group; 200 mg/kg TFLF group; 400 mg/kg TFLF group; 800 mg/kg TFLF group; 150 mg/kg bifendate group; and 800 mg/kg aqueous extract of loquat flower group. The preparations were administered intragastrically at a dose of 0.10 mL/10 g once per day for 10 days; 0.12 mL/10 g body weight of 50% (V/V) dehydrated alcohol was administrated intragastrically at 2 hours after the last administration of the preparations except the normal group. Then the animals were fasted for 16 hours.

The animals were sacrificed, and 0.5 mL of venous blood was collected from the eye socket vein. The liver, spleen, thymus, and kidney were dissected and weighed. 100 mg of hepatic tissue was dissected and homogenated. The concentrations of ALT, AST, and TG in serum and MDA in liver homogenate were determined according to the manufacturer’s instructions.

2.8.2. Detection of RNA expression of adipose triglyceride lipase and Heine oxygenase-1 in liver

Total RNA from liver tissue was isolated using Trizol reagent according to the manufacturer’s instructions (TaKaRa Biotechnology (Dalian) Co., Ltd, 19 Dongbei 2nd street, Development Zone, Dalian, China). The gene expression of adipose triglyceride lipase (ATGL) and Heine oxygenase-1 (HO-1) was measured by real-time quantitative polymerase chain
reaction (PCR), using a model Chromo 4 real-time PCR detection system (Bio-Rad, Hercules, CA, USA). Relative mRNA levels were calculated by the 2\(^{-\Delta\Delta CT}\) method and normalized against β-actin. Primers used in real-time PCR are listed in Table 1.

2.9. Statistical analysis

The results are expressed as mean ± standard deviation. Statistical analyses were done by one-way analysis of variance examined by SPSS version 17.0 (SPSS Inc., Chicago, IL, USA). Values of \( p < 0.05 \) were considered as significantly different, and \( p < 0.01 \) as extremely different.

3. Results

3.1. The optimal extraction procedure of crude flavonoids of loquat flower

The crude flavonoids of loquat flower were extracted by traditional boiling. The optimal conditions of solid–liquid ratio, extraction temperature, decocting time, and number of decoctions were optimized with \( L_9(3^4) \) orthogonal experimentation. Factors and levels are shown in Table 2. As shown in Table 3, the optimal procedure to extract crude flavonoids was: temperature 100°C, decocting time 2.5 hours, solid–liquid ratio 1:20, and decocting three times. The results show that the rank of each factor for extraction from best to least was frequency, temperature, solid–liquid ratio, and extraction time.

3.2. Preparation of TFLF with macroporous resin chromatography

The eluted curve of TFLF from macroporous resin chromatography is shown in Fig. 2. Twenty fractions were collected with volumes of 200 mL. The content of flavonoids in each fraction was measured. The flavonoid content of the four peak fractions collected was 56.06%, 23.62%, 83.69%, and 23.62%. The 30% ethanol fraction had the highest concentration of flavonoids (> 80%); this was collected, vacuum dried, and used as TFLF.

3.3. Component analysis of the total flavonoids

The chromogenic reaction to the flavonoids showed that the water eluent mainly contained phenolic hydroxy group, 4′-OH flavonol or 7, 4′-OH flavonol. The 10% ethanol eluent mainly contained flavanone and flavanone. The 30% ethanol eluent mainly contained flavones, flavonol, flavanone, and flavanone with ortho-phenolic hydroxy group. The 50% ethanol eluent mainly contained the same type of flavonoid, but the specific varieties and contents are different. All of the fractions contained 3-OH, 4-ketone group, or 5-OH, 4-ketone group, but none of them contained anthocyan or chalcone (Table 4).

3.4. The capacity to clear free radicals of the total flavonoids

The ability of the four eluents, the aqueous extract, and the VC control to clear \( \cdot O_2^- \) and \( \cdot OH^- \) is shown in Fig. 3. The clearance of 30% ethanol eluent was 26.09% and 83.01%, respectively, at the dose of 2 mg/mL.

3.5. The effect of TFLF on the levels of ALT, AST, TG, and MDA and organ index

The concentrations of ALT, AST, and TG in serum and MDA in liver homogenate are shown in Table 5. Compared with the normal group, the contents of ALT, AST, TG, and MDA of model groups were increased significantly (\( p < 0.05 \), \( p < 0.05 \), \( p < 0.01 \), and \( p < 0.01 \), respectively), which suggests that the model was successfully made. Comparing with the model group, ALT, TG, and MDA in all of the TFLF treated groups decreased significantly (\( p < 0.05 \), and AST in the 200 mg/kg and 400 mg/kg TFLF treated groups decreased significantly (\( p < 0.01 \) and \( p < 0.05 \), respectively). The effect of TFLF on the organ index is shown in Table 6. Thymus, spleen, and kidney index had no significant change in all groups (\( p > 0.05 \)). Liver index in the model group was increased significantly when compared with the normal control group (\( p < 0.01 \)), and it was decreased significantly in 400 mg/kg and 800 mg/kg TFLF treated groups when compared with the model group (\( p < 0.05 \)). These results suggest that TFLF has advantages of decreasing the levels of AST, ALT, TG, and MDA.

3.6. The effect of TFLF on the expression of hepatic ATGL and HO-1 genes in acute alcoholic liver injury mice

As shown in Fig. 4, compared with the normal group, the mRNA expression of ATGL and HO-1 genes in the model group

was decreased 2.1 times and 2.5 times respectively. Compared with the model group, the ATGL gene expression increased 1.6 times, 1.9 times, and 1.6 times respectively in the 200 mg/kg, 400 mg/kg, and 800 mg/kg TFLF treated groups, and the HO-1 gene expression increased 1.9 times, 2.3 times, and 1.6 times, respectively, in the three TFLF treated groups.

4. Discussion

Loquat flower has a complex chemical composition, in which flavonoids and triterpenes hold a large part. Other active components, such as hemiterpene, polyphenols, glucoside, and aetherolea, are also major active components. Flavonoids are a series of compounds with aromatic ring A and B connected through three central carbon atoms, which can be discriminated by colorable reactions depending on the phenolic hydroxyl group and pyrone ring of the structure. Colorations result indicate that, with the increase of alcohol concentration, the polarity of flavonoids degrades, and the categories also change, illustrating that macroporous adsorptive resins have separated and abstracted the loquat flower flavonoids to a certain degree.

Macroporous adsorptive resins are man-made organic high molecular polymers with a porosity stere-framework. Active components can be abstracted and purified using the principles of aperture, surf-electric charge, and hydrogen bond adsorption. Component selectivity varies under the different polarities and aperture of resins. Generally speaking, semi-polarity macroporous resins contain ester groups that have hydrophilic and hydrophobic parts on the surface, which can absorb nonpolar compounds in polar solvent and polar compounds in nonpolar solvent. They are especially good at separating and purifying organic compounds with pole and low-pole. DM301 is a semi-polarity copolymer of benzene vinyl type, which is suitable for the abstraction of aqueous extract with high polarity. Therefore, through screening four resins (D101, AB-8, DM301, and S-8), we selected DM301 as the optimization resin to do the further study on abstraction and purification of the loquat flower flavones based on the optimization aqua-extract technology.

A free radical is a group that contains an unpaired electron in the external electron orbit and can be produced intracellular, in biolast, endocytoplasmic reticulum, cytoblast and cytochyma, et al. Oxygen inside the cell converts into a superoxide anion free radical when it absorbs the electron, and generates various kinds of free radicals, such as peroxy radical, hydroxyl radical, and alcoxyl radical, which are very active and easy to attack soma, glandular organs, cells (cell envelope), and biomacromolecules, leading to oxidative damage [10]. In the aspect of antioxidation mechanism, flavonoids are considered to turn to semiquinone free radicals, which have a more stable structure after the reaction between phenolic hydroxyl groups and free radicals, and the chain reaction is thus terminated.

Generally speaking, phenolic hydroxyl groups of ring B have the highest antioxygen activity, ring B ranks the second, and ring A is the weakest [11]. In recent years, antioxidant active component studies on loquat flowers mainly focus on aqueous or alcohol extract. Yan et al [12] determined the antioxidant activity of the phenolics of loquat flowers by measuring DPPH (1,1-Diphenyl-2-picrylhydrazyl radical 2,2-
Diphenyl-1-(2,4,6-trinitrophenyl)hydrazyl), ABTS (2,2’-azino-bis(3-ethylbenzthiazoline-6-sulfonic acid), FRAP (ferric reducing antioxidant power), and F-C (Friedel-Crafts acylation). The entire test indicated that the antioxidant activity of aqueous and methanolic extract is higher than that of ethanol. Zhou et al [13] confirmed that flavonoids and polyphenols have a better antioxidant activity. We used macro-porous adsorptive resins to get further abstraction of the flavonoids based on the aqueous extract of loquat flowers, adopting measures of ortho-oxybenzoic acid and pyrogallic autoxidation to determine the antioxygen activity. The result indicates that after ethanol gradient elution, each composition had a marked change on eliminating superoxide radical anion and hydroxy radical compared to aqueous extract, the composition of 30% ethanol elution has the highest activity of antioxygen activity.

There are 22 kinds of amino acids participating in transamination reactions in the human body and each demands a distinct aminopherase. ALT and AST are the two important aminopherases in liver, and they mostly reside in endochylema and mitochondrion. After heavy drinking, the alcohol and its metabolic products may have a direct toxic effect on the hepatic cell, which would cause a rise of the permeability of the cell membrane, leading to the emission (as high as 65%) of aminopherase, and thus increase the content of the two enzymes in blood serum. Therefore, the content of aminopherase in blood serum is one of the most direct and sensitive indexes to reflect the cellular damage of hepatocyte [14]. In addition, excess $H^+$ emerging during the metabolic process of alcohol in liver could promote increased synthesis of $\alpha$-glycerol-phosphoric acid and fatty acid, and decreased fatty acid catabolism, leading to faster TG synthesis, which is then deposited in the liver and results in fatty substance metabolism abnormality. The deposition of TG in the liver will assemble into very low-density lipoprotein, which is then delivered into the blood and will thus increase the level of TG.

As the end product of lipid preoxidation, MDA may reflect the preoxidative degree of the free radicals in vivo. Therefore, changes in MDA content can indicate the damage of cells indirectly [15]. ATGL, the key enzyme of the first step in adipose decomposition, is mainly responsible for converting TG to diglyceride, while it has little effect on lipolysis of other lipids. HO-1 also called heat shock protein 32, is a highly inducible, stress-responsive protein. It catalyzes the first and rate-limiting step in heme degradation. Heme is a potent oxidant, and the induction of HO-1 can provide cytoprotection against oxidative stress. The results show that loquat flower aqueous extract and its flavonoids have effect of reducing the levels of ALT, AST, TG, MDA on the acute alcoholic liver injury mice, and the mechanism is associated with the upregulation of ATGL and HO-1 expression.

Fig. 4 – The effect of TFLF on the relative expression of ATGL and HO-1 mRNA. * Compared with the model group, there is a significant difference if the expression quantity of ATGL or HO-1 is more than 2 times.

Conflicts of interest
