Background: Myocardial infarction with ST segment elevation (STEMI) is a medical emergency requiring specific management aiming to achieve reperfusion as early as possible.

Aims: We aimed to evaluate the temporal trends between 2002 and 2010 in STEMI management and time delays in an eastern region of France (Cote d’Or).

Methods: All consecutive patients admitted for a first STEMI in the RICO survey (Observatoire des Infarctus de Côte d’Or) from 1st January 2002 to 31st December 2010 have been included. We analysed trends in pre-hospital and hospital management times and reperfusion.

Results: 4114 STEMI patients were included over the study period. Mean age and GRACE risk score increased from 2002 to 2010 (64 to 67 y, p=0.001 and 152 to 155 p=0.049). At symptom onset, there was an increase in the rate of patients who called the emergency number (dial 15) and a decrease in the rate of call to GP as first medical contact (from 24.8 to 39.4% and from 57.1 to 42.9%, respectively). However, prehospital times including patient time (from onset of symptoms to call for medical seeking) remained stable over time. There was a significant difference in time to first medical contact according to age, with patients aged under 50 years getting help on average 40 to 100 minutes earlier than patients aged over 50 years. (p=0.019). The average time from first medical contact to reperfusion decreased significantly from 339 minutes in 2002 to 239 minutes in 2010 (p=0.009). Over the study period, there was an inversion in the distribution of reperfusion strategies, with a decrease in fibrinolysis and an increase in primary PCI (from 35% to 27% and from 23.1 to 36.7%, respectively). The rate of patients without acute reperfusion dropped from 41.9 to 36.3% (p=0.001). We found a marked improvement in time to reperfusion including fibrinolysis and door to balloon time (from 150 to 120 min and from 70 to 45 min, respectively).

Conclusion: Between 2002 and 2010, despite marked improvements in management including reperfusion strategies, there is still a room for improvement in order to achieve earlier reperfusion in STEMI patients.

Socio-professional status as a major determinant of disparities in cardiovascular outcomes: contemporary data on the prognosis of workmen after an acute myocardial infarction

Background: Hyperglycemia has been shown to be a powerful predictor of worse outcome after ST segment-elevation myocardial infarction (STEMI).

The aim of this study was to investigate the relation between acute hyperglycemia and angiographic and clinical outcome after primary or rescue angioplasty for STEMI.

Methods: We prospectively included 383 patients who underwent revascularization for STEMI: 332 primary angioplasty and 51 rescue angioplasty. Plasma glucose was measured at hospital admission. Acute hyperglycemia (HG) was defined as plasma glucose of 11 mmol/L, regardless of the diabetic status.

Results: Among the 383 patients with STEMI included in the study, 158 (41.2%) patients had acute hyperglycemia. There was no difference among the two groups with regard to clinical characteristics, cardiovascular risk factors and hemodynamic parameters. Angioplasty success, TIMI 3 flow and ST segment resolution were significantly lower in acute HG group. On multivariate regression, HG wasn’t found to be an independent predictor of angioplasty success (p=0.08; OR=0.9; 95%IC [0.92-1]) or of ST segment resolution after achieving TIMI 3 flow (OR= 3.2; 95% CI [1.02 – 8.1]; p=0.014). Acute hyperglycemia (OR: 3.8; p=0.005) was found to be an independent predictor of in-hospital mortality in multivariate analysis. Among the HG patients, mortality predictors were: glycemia level (OR=1.13; 95%CI [1.03-1.23]; p=0.014), acute hemoglobin level (OR: 0.69; 95%CI [0.53 – 0.9]; p=0.007), and angioplasty success (OR: 0.25; 95%CI [0.08-0.82]; p=0.022).

Conclusion: Acute hyperglycemia in patients with STEMI is an important predictor of mortality with an increasing mortality risk even beyond 11 mmol/L but diabetes is a better predictor of ST resolution after TIMI 3 restoring. This suggests the usefulness of assessment of glycemic metabolism in the setting of reperfusion for acute myocardial infarction and the beneficial effect of strict glycemic control.
