Conclusions: We found significant correlations of IVUS-VH determined atherosclerotic plaque components between coronary and carotid arteries in patients with atherosclerosis involving both arterial beds.

Background: The frequency, type and extent of neoatherosclerosis within drug-eluting stents (DES) has not been described during very long-term follow-up. Moreover, it is unknown whether DES eluting sirolimus differ from those eluting paclitaxel in the propensity for neoatherosclerosis during long-term follow-up.

Methods: The SIRTAX LATE OCT population was analyzed for evidence of neoatherosclerosis within stented segments five years after DES implantation. Using OCT definitions according to the Consensus Statement of the International Working Group of OCT, we assessed the presence of fibrocalcific plaques, fibroatheromas, macrophage accumulations, microvessels, as well as surface erosions and ruptures in each single frame. Plaques were considered to be present in case of a longitudinal extension of at least 1mm, and all other findings had to be visualized in at least three consecutive frames.

Results: All segments were independently assessed by two experienced observers. A total of 89 event-free patients with 41 lesions treated with SES (41 patients) and 48 lesions treated with PES (47.9% vs. 25%) than SES (5%; P < 0.05), minimal lumen area (1.95 ± 1.21, 2.68 ± 1.31), cavity area (1.87 ± 1.28, 3.09 ± 1.02, p < 0.05), proximal lumen area (6.76 ± 2.24, 10.72 ± 3.74, p < 0.05) Location of plaque rupture site was: proximal (group P: 66%, group D: 38%); middle (25%, 12%); distal (9%, 30%, p < 0.05). There was no difference determined between groups for location of MLA or residual low intensity area. Furthermore, there was a higher tendency for group D to have spotty calcification at lesion location compared to Group P (50%, 88%, respectively).

Conclusions: In comparison to those patients with proximal cavity aperture, distal cavity aperture patients had larger vessel diameter, larger plaque volume and plaque disruption distal to lesion location.

Impact of the Prevalence of Diabetes Mellitus on Coronal Plaque Vulnerability Assessed by Integrated Backscatter Intravascular Ultrasound

Atsushi Iwata1, Saku Keijiro2
1Fukuoka University school of medicine, Fukuoka, Japan, 2Fukuoka university school of medicine, Fukuoka, Japan

Background: Diabetes mellitus (DM) is a well-established risk factor for coronary artery disease (CAD). However, little is known about relationship the prevalence of DM and coronary plaque vulnerability assessed by integrated backscatter intravascular ultrasound (IB-IVUS).

Methods: One hundred sixteen consecutive patients with stable CAD who underwent percutaneous coronary intervention were enrolled. Nonculprit coronary lesions with mild to moderate stenoses were measured by IB-IVUS. A total of 20 IB-IVUS images were recorded at an interval of 0.5 mm for 10 mm length in each plaque. Patients were divided into two groups: the DM group and the non-DM group. We assessed the relations among DM and coronary plaque instability using IB-IVUS.

Results: Plaque volume (PV) and percentage of PV (%PV; 100%PV/Vessel Diameter) in the DM group were significantly higher than those in the non-DM group (66.0 ± 22.7 mm3 vs. 56.8 ± 21.2 mm3, P = 0.0278 and 42.5 ± 9.7% vs. 39.0 ± 8.8%, P = 0.0453, respectively). Lipid volume (LV) and percentage of LV (%LV; 100%LV/Vascular Diameter) in the DM group were significantly higher than those in the non-DM group (28.9 ± 15.5 mm3 vs. 22.2 ± 13.0 mm3, P = 0.0130 and 42.1 ± 12.4% vs. 37.3 ± 12.2%, P = 0.0400, respectively). Furthermore, multiple regression analysis revealed that the prevalence of DM was independently associated with PV (p = 0.0351), LV (p = 0.0164) and %LV (p = 0.0304) among IVUS parameters in addition to other metabolic factors.

Conclusions: Nonculprit coronary lesions in patients with DM are associated with more lipid-rich plaque content and a greater PV, suggesting that DM patients increased plaque vulnerability.

Clinical Feasibility of Higher-Frequency IVUS for Quantitative Measurements of Native Coronary Lesions: First-in-Human Experience with 60MHz versus 40MHz IVUS Imaging

Ching-Chang Huang1, Kenji Sakamoto1, Kaori Nakagawa1, Paul Yock1, Adrian Ebner2, Peter Fitzgerald1, Fumiaki Ikeno1, Yasuhito Honda1

Background: Despite the technical advantage of improved image resolutions, higher-frequency IVUS imaging may theoretically be susceptible to impaired lumen and vessel border detection due to higher blood scattering and lower signal penetration within the tissue. This first-in-human study aimed to evaluate the feasibility of 60MHz IVUS imaging with a novel multi-frequency IVUS system in vivo-quantitative assessment of native coronary lesions.

Methods: A total of 121 matched cross-sections were imaged and compared at 40MHz and 60MHz. Visibility of lumen and vessel borders were classified into 3 grades (good: entire circumference visible, fair: ≥75% visible, and poor: <75% visible). Quantitative evaluation included area and minimum diameter measurements of lumen (LA; MLD) and vessel (VA; MVD).

Results: Good visualization of lumen border was achieved in 87.6% with 60MHz compared to 79.3% with 40MHz (P = 0.08), while the rates of good vessel border detection were similar between the 2 frequency groupings (p = 0.79). Overall, the 40MHz and 60MHz imagings showed comparable visibilities of lumen and vessel borders. All quantitative measurements significantly correlated with good agreements (LA: r = 0.97; MLD: r = 0.95; VA: r = 0.97; MVD: r = 0.93, P < 0.001 for all) between the 2 frequency imagings.
