#### Abstract

Double-loop networks have been widely studied as architecture for local area networks and it is well-known that the minimum distance diagram of a double-loop network yields an L-shape. Given an $N$, it is desirable to find a double-loop network $D L\left(N ; s_{1}, s_{2}\right)$ with its diameter being the minimum among all double-loop networks with $N$ stations. Since the diameter can be easily computed from an L-shape, one method is to start with a desirable L-shape and then asks whether there exist $s_{1}$ and $s_{2}$ (also called the steps of the double-loop network) to realize it. In this paper, we propose a simple and efficient algorithm to find $s_{1}$ and $s_{2}$, which is based on the Smith normalization method of Aguiló, Esqué and Fiol. © 2002 Elsevier Science B.V. Keywords: Double-loop network; L-shape; Diameter; Algorithm

## 1. Introduction

A double-loop network $D L\left(N ; s_{1}, s_{2}\right)$ has $N$ nodes $0,1, \ldots, N-1$ and $2 N$ links of two types:

$$
\begin{aligned}
& s_{1} \text {-links }: i \rightarrow i+s_{1}(\bmod N), \quad i=0,1, \ldots, N-1, \\
& s_{2} \text {-links }: i \rightarrow i+s_{2}(\bmod N), \quad i=0,1, \ldots, N-1
\end{aligned}
$$

Double-loop networks have been widely studied as architecture for local area networks. For surveys about these networks, see [2,10,11,14].

Fiol et al. [8] proved that $D L\left(N ; s_{1}, s_{2}\right)$ is strongly connected if and only if $\operatorname{gcd}\left(N, s_{1}, s_{2}\right)=1$. When $D L\left(N ; s_{1}, s_{2}\right)$ is strongly connected, then we can talk about

Fig. 2. An L-shape with parameters.
a minimum distance diagram. This diagram gives a shortest path from node $u$ to node $v$ for any $u, v$. Since a double-loop network is node-symmetric, it suffices to give a shortest path from node 0 to any other node. Let 0 occupy cell $(0,0)$. Then $v$ occupies cell $(i, j)$ if and only if $i a+j b \equiv v(\bmod N)$ and $i+j$ is the minimum among all $\left(i^{\prime}, j^{\prime}\right)$ satisfying the congruence, where $\equiv$ means congruent modulo $N$. Namely, a shortest path from 0 to $v$ is through taking $i s_{1}$-links and $j s_{2}$-links (in any order). Note that in a cell $(i, j), i$ is the column index and $j$ is the row index. A minimum distance diagram includes every node exactly once (in case of two shortest paths, the convention is to choose the cell with the smaller row index, i.e., the smaller $j$ ). Wong and Coppersmith [15] proved that the minimum distance diagram is always an L-shape (a rectangle is considered a degeneration). See Fig. 1 for two examples.

An L-shape is determined by four parameters $l, h, p, n$ as shown in Fig. 2. These four parameters are the lengths of four of the six segments on the boundary of the L-shape. For example, $D L(9 ; 4,1)$ in Fig. 1 has $l=5, h=3, p=3$, and $n=2$. Let $N=l h-p n$. Fiol et al. [8,9] and Chen and Hwang [3] proved that there exists a $\operatorname{DL}\left(N ; s_{1}, s_{2}\right)$ realizing the L-shape $(l, h, p, n)$ if and only if $l>n, h \geqslant p$, and $\operatorname{gcd}(l, h, p, n)=1$.

The diameter $d\left(N ; s_{1}, s_{2}\right)$ of a double-loop network $D L\left(N ; s_{1}, s_{2}\right)$ is the largest distance between any pair of stations. It represents the maximum transmission delay between two stations. Therefore, it is desirable to minimize the diameter. This is the problem discussed by many authors; see [1,5-7,9,12,15]. Let $d(N)$ denote the best possible diameter of a double-loop network with $N$ stations. Wong and Coppersmith [15] showed that $d(N) \geqslant\lceil\sqrt{3 N}\rceil-2$.

Given an $N$, it is desirable to find a double-loop network $D L\left(N ; s_{1}, s_{2}\right)$ with its diameter being equal to $d(N)$. Since the diameter of a double-loop network $D L\left(N ; s_{1}, s_{2}\right)$
can be readily computed from the dimensions of its L-shape, one method is to start with a desirable L-shape and then asks whether there exist $s_{1}$ and $s_{2}$ to realize it. Aguiló, Esqué and Fiol [1,7] proposed the Smith normalization method to find $s_{1}$ and $s_{2}$ for a given L-shape, but no explicit algorithm was given in their paper. In [3], Chen and Hwang proposed a simple method, based on the sieve method in number theory, to find $s_{1}$ and $s_{2}$ for a given L-shape.

In this paper, we propose a simple and efficient algorithm to find $s_{1}$ and $s_{2}$ for a given L-shape. Our algorithm is based on the Smith normalization method of Aguiló, Esqué and Fiol [1,7], but unlike their method, our algorithm does not require any matrix operation. Our algorithm takes at most $\mathrm{O}\left((\log N)^{2}\right)$ time and if $\operatorname{gcd}(l, n)=1$ or $\operatorname{gcd}(l, p)=1$ or $\operatorname{gcd}(h, p)=1$ or $\operatorname{gcd}(h, n)=1$, then our algorithm could find the steps of a double-loop network in only $\mathrm{O}(\log N)$ time.

## 2. Preliminary

It is well-known that
Lemma 1. If $a$ and $b$ are integers, not both zero, then there exist integers $\alpha$ and $\beta$ such that $\alpha a+\beta b=\operatorname{gcd}(a, b)$.

We now prove that
Lemma 2. If $\alpha, a, \beta, b$ are integers, not all zero, such that $\alpha a+\beta b=1$, then $\operatorname{gcd}(a, \beta)=1$.
Proof. Assume that $\alpha a+\beta b=1$ and $\operatorname{gcd}(a, \beta)=k$. Then $k \mid a$ and $k \mid \beta$. Thus $k \mid \alpha a+$ $\beta b=1$. So $k=1$.

Theorem 3. If $a$ and $b$ are integers, not both zero, then there exist integers $x$ and $y$ such that $x a+y b=\operatorname{gcd}(a, b)$ and $(y, \operatorname{gcd}(a, b))=1$.

Proof. Set $r=\operatorname{gcd}(a, b)$ for easy writing. By Lemma 1, there exist integers $\alpha$ and $\beta$ such that $\alpha a+\beta b=r$. If $\operatorname{gcd}(\beta, r)=1$, then we are done. In the following, assume that $\operatorname{gcd}(\beta, r)=k>1$. Suppose $k=p_{1}^{s_{1}} p_{2}^{s_{2}} \cdots p_{m}^{s_{m}}$, where $p_{1}<p_{2}<\cdots<p_{m}$ are the prime factors of $k$ and suppose $r=p_{1}^{r_{1}} p_{2}^{r_{2}} \cdots p_{m}^{r_{m}} p_{m+1}^{r_{m+1}} p_{m+2}^{r_{m+2}} \cdots p_{n}^{r_{n}}$, where $p_{1}<p_{2}<\cdots<p_{n}$ are the prime factors of $r$. Since $k \mid r$, we have $r_{i} \geqslant s_{i}$ for all $i, 1 \leqslant i \leqslant m$. Let

$$
r^{\prime}=p_{m+1}^{r_{m+1}} p_{m+2}^{r_{m+2}} \cdots p_{n}^{r_{n}}, \quad a^{\prime}=a / r, \text { and } b^{\prime}=b / r
$$

Note that $\operatorname{gcd}\left(r^{\prime}, \beta\right)=1$; otherwise, we will have $\operatorname{gcd}(\beta, r)>k$. Since $\operatorname{gcd}\left(r^{\prime}, \beta\right)=1$ and $k \mid \beta$, we have $\operatorname{gcd}\left(r^{\prime}, k\right)=1$. Since $\alpha a+\beta b=r$, we have $\alpha a^{\prime}+\beta b^{\prime}=1$. By Lemma 2 , we have $\operatorname{gcd}\left(a^{\prime}, \beta\right)=1$. Since $\operatorname{gcd}\left(a^{\prime}, \beta\right)=1$ and $k \mid \beta$, we have $\operatorname{gcd}\left(a^{\prime}, k\right)=1$. Since $k \mid \beta$ and $\operatorname{gcd}\left(r^{\prime}, k\right)=1$ and $\operatorname{gcd}\left(a^{\prime}, k\right)=1$, we have $\operatorname{gcd}\left(\beta-r^{\prime} a^{\prime}, k\right)=1$. Since $\operatorname{gcd}\left(r^{\prime}, \beta\right)$ $=1$ and $r^{\prime} \mid r^{\prime} a^{\prime}$, we have $\operatorname{gcd}\left(\beta-r^{\prime} a^{\prime}, r^{\prime}\right)=1$. Since $\operatorname{gcd}\left(\beta-r^{\prime} a^{\prime}, k\right)=1$ and
$\operatorname{gcd}\left(\beta-r^{\prime} a^{\prime}, r^{\prime}\right)=1$ and every prime factor of $r$ is either a prime factor of $k$ or a prime factor of $r^{\prime}$, we have $\operatorname{gcd}\left(\beta-r^{\prime} a^{\prime}, r\right)=1$. Consider

$$
x=\alpha+r^{\prime} b^{\prime} \quad \text { and } \quad y=\beta-r^{\prime} a^{\prime}
$$

Then $x a+y b=\left(\alpha+r^{\prime} b^{\prime}\right) a+\left(\beta-r^{\prime} a^{\prime}\right) b=r$ and $\operatorname{gcd}(y, r)=\operatorname{gcd}\left(\beta-r^{\prime} a^{\prime}, r\right)=1$. We have this theorem.

The proof of Theorem 3 leads to the following algorithm for finding $x$ and $y$ in Theorem 3.

## ALGORITHM-MODIFIED-EUCLIDEAN

Input: Integers $a$ and $b$, not both zero, and $r=\operatorname{gcd}(a, b)$.
Output: Integers $x$ and $y$ such that $x a+y b=r$ and $\operatorname{gcd}(y, r)=1$.

1. Find integers $\alpha$ and $\beta$ such that $\alpha a+\beta b=r$.
2. If $\operatorname{gcd}(\beta, r)=1$, then let $x=\alpha, y=\beta$, return $x, y$ and stop this algorithm.
3. Let $k=\operatorname{gcd}(\beta, r), r^{\prime}=r$, and $d=k$.
4. WHILE $(d>1)$ DO

BEGIN
$r^{\prime}=r^{\prime} / d$;
$d=\operatorname{gcd}\left(r^{\prime}, k\right)$;
END
5. Let $a^{\prime}=a / r, b^{\prime}=b / r, x=\alpha+r^{\prime} b^{\prime}$ and $y=\beta-r^{\prime} a^{\prime}$. Return $x, y$.

We give an example to show how Step 4 is executed. Suppose before Step 4 is executed, $d=k=2^{3} \times 3^{2} \times 7^{4}$ and $r^{\prime}=r=2^{4} \times 3^{8} \times 7^{15} \times 11 \times 23$. After the first iteration of the while-loop, $r^{\prime}=2 \times 3^{6} \times 7^{11} \times 11 \times 23$ and $d=2 \times 3^{2} \times 7^{4}$. After the second iteration, $r^{\prime}=3^{4} \times 7^{7} \times 11 \times 23$ and $d=3^{2} \times 7^{4}$. After the third iteration, $r^{\prime}=3^{2} \times 7^{3} \times 11 \times 23$ and $d=3^{2} \times 7^{3}$. After the fourth iteration, $r^{\prime}=11 \times 23$ and $d=1$. Since $d=1$, we stop the iteration.

Theorem 4. ALGORITHM-MODIFIED-EUCLIDEAN is correct and it takes at most $\mathrm{O}\left((\log N)^{2}\right)$ time, where $N=\max \{a, b\}$.

Proof. Note that Steps 1, 2, 3, and 5 of ALGORITHM-MODIFIED-EUCLIDEAN are translated directly from the proof of Theorem 3, so they are correct. Steps 1 and 2 take $\mathrm{O}(\log N)$ time; Steps 3 and 5 take $\mathrm{O}(1)$ time. It remains to consider Step 4. Let $k=p_{1}^{s_{1}} p_{2}^{s_{2}} \cdots p_{m}^{s_{m}}$ and $r=p_{1}^{r_{1}} p_{2}^{r_{2}} \cdots p_{m}^{r_{m}} p_{m+1}^{r_{m+1}} p_{m+2}^{r_{m+2}} \cdots p_{n}^{r_{n}}$ be defined as in the proof of Theorem 3. Note that $r_{i} \geqslant s_{i}$ for all $i, 1 \leqslant i \leqslant m$. In the proof of Theorem 3, we need $r^{\prime}=p_{m+1}^{r_{m+1}} p_{m+2}^{r_{m+2}} \cdots p_{n}^{r_{n}}$. The purpose of Step 4 is to derive $r^{\prime}=p_{m+1}^{r_{m+1}} p_{m+2}^{r_{m+2}} \cdots p_{n}^{r_{n}}$.

Before Step 4 is executed, $r^{\prime}=r=p_{1}^{r_{1}} p_{2}^{r_{2}} \cdots p_{m}^{r_{m}} p_{m+1}^{r_{m+1}} p_{m+2}^{r_{m+2}} \cdots p_{n}^{r_{n}}$. We then use a while-loop to remove $p_{1}^{r_{1}} p_{2}^{r_{2}} \cdots p_{m}^{r_{m}}$ from $r^{\prime}$. Before an iteration of the while-loop, if $p_{i}$ (where $1 \leqslant i \leqslant m$ ) still exists in the current $r^{\prime}$ and its power in the current $r^{\prime}$ is
$r_{i}^{\prime}$, then after the iteration, the power of $p_{i}$ is decreased by $s_{i}$ or $r_{i}^{\prime}$, whichever is smaller. At the end of Step 4, $d=\operatorname{gcd}\left(r^{\prime}, k\right)=1$; that is, $r^{\prime}=p_{m+1}^{r_{m+1}} p_{m+2}^{r_{m+2}} \cdots p_{n}^{r_{n}}$. Set $\rho=\max \left\{\left\lceil r_{1} / s_{1}\right\rceil,\left\lceil r_{2} / s_{2}\right\rceil, \ldots,\left\lceil r_{m} / s_{m}\right\rceil\right\}$ for easy writing. Step 4 iterates $\rho$ times. Thus Step 4 takes $\mathrm{O}(\rho \log N)$ time. Since $\rho=\mathrm{O}(\log N)$, Step 4 takes at most $\mathrm{O}\left((\log N)^{2}\right)$ time.

The above arguments show that ALGORITHM-MODIFIED-EUCLIDEAN is correct and it takes at most $\mathrm{O}\left((\log N)^{2}\right)$ time.

## 3. The Smith normalization method

Let $L(l, h, p, n)$ be an L-shape such that $l>n, h \geqslant p$, and $\operatorname{gcd}(l, h, p, n)=1$. Aguiló and Fiol [1], and also Esqué et al. [7] proposed the following method of computing $s_{1}$ and $s_{2}$ such that $D L\left(N ; s_{1}, s_{2}\right)$ realizes $L$. They considered the integral matrix

$$
\mathscr{M}=\left(\begin{array}{cc}
l & -p \\
-n & h
\end{array}\right)
$$

and computed the Smith normal form of $\mathscr{M}$,

$$
\mathscr{S}(\mathscr{M})=\left(\begin{array}{cc}
1 & 0 \\
0 & N
\end{array}\right) .
$$

Then $\mathscr{L}(\mathscr{M})=\mathscr{L} \mathscr{M} \mathscr{R}$, where $\mathscr{L}$ and $\mathscr{R}$ are two nonsingular unimodular (determinant $\pm 1)$ integral matrices. They proved that if

$$
\mathscr{L}=\left(\begin{array}{ll}
\alpha & \beta \\
\gamma & \delta
\end{array}\right)
$$

then $s_{1}=\gamma(\bmod N)$ and $s_{2}=\delta(\bmod N)$ in $D L\left(N ; s_{1}, s_{2}\right)$. No algorithm on computing the Smith normal form was actually given in their paper except a reference to [13]. In [13], the reader was referred to three theorems (Theorem II.1, Theorem II.2, and Theorem II.9) for learning how to compute the Smith normal form.

The following is a brief description of what the three theorems in [13] say. Let $\alpha_{1}$ and $\alpha_{2}$ be two integers, no both zero, and let $\delta=\operatorname{gcd}\left(\alpha_{1}, \alpha_{2}\right)$. Theorem II. 1 says that there exists an integral matrix

$$
\left(\begin{array}{cc}
\alpha_{1} & \alpha_{2} \\
\sigma & \rho
\end{array}\right)
$$

with first row $\left[\alpha, \alpha_{2}\right]$ and determinant $\delta$; note that the elements $\sigma$ and $\rho$ may be determined by the Euclidean algorithm. Theorem II. 2 uses Theorem II. 1 to show that the $(1,1)$ element of a matrix may be replaced by the greatest common divisor of the first column of the matrix. Theorem II. 9 uses Theorem II. 2 to derive the Smith normal form. To make the readers easy to understand the Smith normalization method, we now give an explicit algorithm for it.

## THE-SMITH-NORMALIZATION-METHOD

Input: $l, h, p, n$ of an L-shape $L$, where $l>n, h \geqslant p$, and $\operatorname{gcd}(l, h, p, n)=1$.
Output: $s_{1}$ and $s_{2}$ such that $\operatorname{DL}\left(N ; s_{1}, s_{2}\right)$ realizes the L-shape $L(l, h, p, n)$.

1. Let

$$
\begin{gathered}
\mathscr{M}=\left(\begin{array}{cc}
l & -p \\
-n & h
\end{array}\right), \\
\mathscr{M}_{0}=\mathscr{M}, i=0, j=0, k=0 .
\end{gathered}
$$

2. Repeat sub-steps 2.1-2.2 until the $(1,1)$ element of $\mathscr{M}_{j}$ divides both the $(2,1)$ element and the (1,2) element of $\mathscr{M}_{j}$.
2.1 If the $(1,1)$ element of $\mathscr{M}_{j}$ does not divide the $(2,1)$ element of $\mathscr{M}_{j}$, then let $i=i+1, j=j+1$, and find a nonsingular unimodular integral matrix $\mathscr{L}_{i}$ such that the $(1,1)$ element of $\mathscr{M}_{j}=\mathscr{L}_{i} \mathscr{M}_{j-1}$ is the greatest common divisor of the first column of $\mathscr{M}_{j-1}$.
2.2 If the $(1,1)$ element of $\mathscr{M}_{j}$ does not divide the (1,2) element of $\mathscr{M}_{j}$, then let $j=j+1, k=k+1$, and find a nonsingular unimodular integral matrix $\mathscr{R}_{k}$ such that the $(1,1)$ element of $\mathscr{M}_{j}=\mathscr{M}_{j-1} \mathscr{R}_{k}$ is the greatest common divisor of the first row of $\mathscr{M}_{j-1}$.
3. If the (2,1) element of $\mathscr{M}_{j}$ is not zero, then let $i=i+1, j=j+1$, and find a nonsingular unimodular integral matrix $\mathscr{L}_{i}$ to make the (2,1) element of $\mathscr{M}_{j}=\mathscr{L}_{i} \mathscr{M}_{j-1}$ zero.
4. If the ( 1,2 ) element of $\mathscr{M}_{j}$ is not zero, then let $j=j+1, k=k+1$, and find a nonsingular unimodular integral matrix $\mathscr{R}_{k}$ to make the (1,2) element of $\mathscr{M}_{j}=\mathscr{M}_{j-1} \mathscr{R}_{k}$ zero.
5. If the $(1,1)$ element of $\mathscr{M}_{j}$ does not divide the (2,2) element of $\mathscr{M}_{j}$, then add column 2 of $\mathscr{M}_{j}$ to column 1 of $\mathscr{M}_{j}$ and go to Step 2.
6. Now $\mathscr{M}_{j}$ is the Smith normal form of $\mathscr{M}$, i.e.,

$$
\mathscr{M}_{j}=\mathscr{L}_{i} \cdots \mathscr{L}_{2} \mathscr{L}_{1} \mathscr{M} \mathscr{R}_{1} \mathscr{R}_{2} \ldots \mathscr{R}_{k}=\mathscr{S}(\mathscr{M})=\left(\begin{array}{cc}
1 & 0 \\
0 & N
\end{array}\right) .
$$

Let $\mathscr{L}=\mathscr{L}_{i} \cdots \mathscr{L}_{2} \mathscr{L}_{1}$. If

$$
\mathscr{L}=\left(\begin{array}{ll}
\alpha & \beta \\
\gamma & \delta
\end{array}\right)
$$

then let $s_{1}=\gamma(\bmod N)$ and let $s_{2}=\delta(\bmod N)$. Return $s_{1}, s_{2}$.
Since $[1,7]$ did not provide the time complexity analysis of the Smith normalization method, we now analyze its time complexity. Its time complexity is dominated by Step 2. Each execution of Step 2 takes $\mathrm{O}(\log N)$ time. Since each execution of Step 2.1 and Step 2.2 makes the $(1,1)$ element of $\mathscr{M}_{j}$ contains less prime factors than before, Step 2 is executed at most $\mathrm{O}(\log N)$ times. Therefore the Smith normalization method takes at most $\mathrm{O}\left((\log N)^{2}\right)$ time.

## 4. The sieve method

Let $L(l, h, p, n)$ be an L-shape such that $l>n, h \geqslant p$, and $\operatorname{gcd}(l, h, p, n)=1$. Chen and Hwang [3] (see also [11]) proposed the following method, based on the sieve method in number theory, to find $s_{1}$ and $s_{2}$.

For $k=0,1, \ldots$, define

$$
\begin{aligned}
& a_{k}=k n+h, \\
& b_{k}=k l+p .
\end{aligned}
$$

Let $F_{k}$ denote the set of prime factors of $\operatorname{gcd}\left(a_{k}, b_{k}\right)$ and $F$ denote the set of prime factors of $N$. They proved that there exists a $k$ such that $f \notin F_{k}$ for all $f \in F$; then $s_{1}=a_{k}(\bmod N)$ and $s_{2}=b_{k}(\bmod N)$ realize $L$. Note that if $f \in F$ appears in $F_{k}$ for some $k$ and $k_{f}$ is the smallest such $k$, then $f$ appears in every $f$ th $k$ after $k_{f}$.

For example, suppose $N=2 \times 3 \times 5 \times 7 \times 11 \times 59$, and $L(l, h, p, n)=L\left(2^{2} \times 107,2^{2} \times 3 \times\right.$ $\left.5 \times 7,2 \times 3 \times 5 \times 7,3^{2} \times 23\right)$. Then $F_{0}=\{2,3,5,7\}, F_{1}=\{11\}$, and $F=\{2,3,5,7,11,59\}$. Thus
$2 \in F$ appears in $a_{0}, b_{0}, a_{2}, b_{2}, a_{4}, b_{4}, a_{6}, b_{6}, a_{8}, b_{8}$, etc.,
$3 \in F$ appears in $a_{0}, b_{0}, a_{3}, b_{3}, a_{6}, b_{6}, a_{9}, b_{9}$, etc.,
$5 \in F$ appears in $a_{0}, b_{0}, a_{5}, b_{5}, a_{10}, b_{10}, a_{15}, b_{15}$, etc.,
$7 \in F$ appears in $a_{0}, b_{0}, a_{7}, b_{7}, a_{14}, b_{14}, a_{21}, b_{21}$, etc.,
$11 \in F$ appears in $a_{1}, b_{1}, a_{12}, b_{12}, a_{23}, b_{23}, a_{34}, b_{34}$, etc.
The first pair $a_{k}, b_{k}$ that is not crossed out by the sieve method is $a_{11}, b_{11}$. Thus $s_{1}=a_{11}(\bmod N)$ and $s_{2}=b_{11}(\bmod N)$ realize $L$.

The sieve method is simple and easy to implement. Note that [3,11] did not give the time complexity analysis of the sieve method. Although we are also unable to give an exact time complexity analysis for the method, we give an upper bound for it. Let $\eta(N)$ denote the number of prime factors of $N$ and let $P_{i}$ denote the $i$ th prime, i.e., $P_{1}=2, P_{2}=3$, etc. Since smaller primes cross out more pairs $\left(a_{k}, b_{k}\right)$ than larger primes can cross out, the sieve method would take the longest time when $N$ contains the smallest $\eta(N)$ primes. In this case, the final $k$ is bounded above by $P_{\eta(N)}$. Since checking if $f \notin F_{k}$ for all $f \in F$ is equivalent to check if $\operatorname{gcd}\left(\operatorname{gcd}\left(a_{k}, b_{k}\right), N\right)=1$ (which could be checked by using the Euclidean algorithm twice), the sieve method takes at most $\mathrm{O}\left(P_{\eta(N)} \log N\right)$ time.

## 5. Our algorithm

Given an L-shape, we propose the following algorithm to find $s_{1}$ and $s_{2}$.

## ALGORITHM-COMPUTING-STEPS

Input: $l, h, p, n$ of an L-shape $L$, where $l>n, h \geqslant p$, and $\operatorname{gcd}(l, h, p, n)=1$.

Output: $s_{1}$ and $s_{2}$ such that $D L\left(N ; s_{1}, s_{2}\right)$ realizes $L$.

1. Find $r_{1}=\operatorname{gcd}(l,-n)$.
2. Find integers $\alpha_{1}$ and $\beta_{1}$ such that $\alpha_{1} l+\beta_{1}(-n)=r_{1}$.
3. Find $r_{2}=\operatorname{gcd}\left(r_{1},-\alpha_{1} p+\beta_{1} h\right)$.
4. Find integers $\alpha_{2}$ and $\beta_{2}$ such that $\alpha_{2} r_{1}+\beta_{2}\left(-\alpha_{1} p+\beta_{1} h\right)=r_{2}$ and $\operatorname{gcd}\left(\beta_{2}, r_{2}\right)=1$.
5. $s_{1}=\alpha_{2} n-\beta_{2} h(\bmod N)$ and $s_{2}=\alpha_{2} l-\beta_{2} p(\bmod N)$.

For example, let $l=5, h=3, p=3$, and $n=2$. Then our algorithm derives $r_{1}=1$, $\alpha_{1}=1, \beta_{1}=2, r_{2}=1, \alpha_{2}=-2$, and $\beta_{2}=1$. Thus $s_{1}=-7(\bmod 9)$ and $s_{2}=-13(\bmod 9)$, i.e., $s_{1}=2$ and $s_{2}=5$. It can be verified that $D L(9 ; 2,5)$ realizes L-shape(5,3,3,2).

We now prove that

Theorem 5. ALGORITHM-COMPUTING-STEPS is correct and it takes at most $\mathrm{O}\left((\log N)^{2}\right)$ time.

Proof. Note that $N=l h-p n$. Let

$$
\mathscr{M}=\left(\begin{array}{cc}
l & -p \\
-n & h
\end{array}\right) .
$$

Consider column 1 of $\mathscr{M}$ : it contains $l$ and $-n$. After Step 1 is performed, we have $r_{1}=\operatorname{gcd}(l,-n)$ and $\alpha_{1} l+\beta_{1}(-n)=r_{1}$. Let

$$
\mathscr{L}_{1}=\left(\begin{array}{cc}
\alpha_{1} & \beta_{1} \\
\frac{n}{r_{1}} & \frac{l}{r_{1}}
\end{array}\right)
$$

and let $\mathscr{M}_{1}=\mathscr{L}_{1} \mathscr{M}$. Then

$$
\mathscr{M}_{1}=\left(\begin{array}{cc}
\alpha_{1} & \beta_{1} \\
\frac{n}{r_{1}} & \frac{l}{r_{1}}
\end{array}\right)\left(\begin{array}{cc}
l & -p \\
-n & h
\end{array}\right)=\left(\begin{array}{cc}
r_{1} & -\alpha_{1} p+\beta_{1} h \\
0 & \frac{N}{r_{1}}
\end{array}\right) .
$$

Consider row 1 of $\mathscr{M}_{1}$ : it contains $r_{1}$ and $-\alpha_{1} p+\beta_{1} h$. After Step 2 is performed, we have $r_{2}=\operatorname{gcd}\left(r_{1},-\alpha_{1} p+\beta_{1} h\right), \alpha_{2} r_{1}+\beta_{2}\left(-\alpha_{1} p+\beta_{1} h\right)=r_{2}$, and $\operatorname{gcd}\left(\beta_{2}, r_{2}\right)=1$. Let

$$
\mathscr{R}_{1}=\left(\begin{array}{cc}
\alpha_{2} & \frac{-\left(-\alpha_{1} p+\beta_{1} h\right)}{r_{2}} \\
\beta_{2} & \frac{r_{1}}{r_{2}}
\end{array}\right) .
$$

and let $\mathscr{M}_{2}=\mathscr{M}_{1} \mathscr{R}_{1}$. Then

$$
\mathscr{M}_{2}=\left(\begin{array}{cc}
r_{1}-\alpha_{1} p+\beta_{1} h \\
0 & \frac{N}{r_{1}}
\end{array}\right)\left(\begin{array}{cc}
\alpha_{2} & \frac{-\left(-\alpha_{1} p+\beta_{1} h\right)}{r_{2}} \\
\beta_{2} & \frac{r_{1}}{r_{2}}
\end{array}\right)=\left(\begin{array}{cc}
r_{2} & 0 \\
\frac{N \beta_{2}}{r_{1}} & \frac{N}{r_{2}}
\end{array}\right) .
$$

Consider column 1 of $\mathscr{M}_{2}$ : it contains $r_{2}$ and $N \beta_{2} / r_{1}$. Let $r_{3}=\operatorname{gcd}\left(r_{2}, N \beta_{2} / r_{1}\right)$. Note that in Step 2 we choose $\operatorname{gcd}\left(\beta_{2}, r_{2}\right)=1$. Thus

$$
r_{3}=\operatorname{gcd}\left(r_{2}, \frac{N \beta_{2}}{r_{1}}\right)=\operatorname{gcd}\left(r_{2}, \frac{N}{r_{1}}\right)=\operatorname{gcd}\left(r_{1},-\alpha_{1} p+\beta_{1} h, \frac{N}{r_{1}}\right)
$$

We claim that $r_{3}=1$. Suppose this is not true and $r_{3}>1$. Then every entry of $\mathscr{M}_{1}$ is a multiple of $r_{3}$. Since $\mathscr{M}_{1}=\mathscr{L}_{1} \mathscr{M}$, we have

$$
\mathscr{M}=\mathscr{L}_{1}^{-1} \mathscr{M}_{1}=\frac{1}{\operatorname{det}\left(\mathscr{L}_{1}\right)}\left(\begin{array}{cc}
\frac{l}{r_{1}} & -\beta_{1} \\
-\frac{n}{r_{1}} & \alpha_{1}
\end{array}\right)\left(\begin{array}{cc}
r_{1} & -\alpha_{1} p+\beta_{1} h \\
0 & \frac{N}{r_{1}}
\end{array}\right) .
$$

That is,

$$
\mathscr{M}=\frac{1}{\operatorname{det}\left(\mathscr{L}_{1}\right)}\left(\begin{array}{cc}
\frac{l}{r_{1}} & -\beta_{1} \\
-\frac{n}{r_{1}} & \alpha_{1}
\end{array}\right) r_{3}\left(\begin{array}{cc}
\frac{r_{1}}{r_{3}} & \frac{-\alpha_{1} p+\beta_{1} h}{r_{3}} \\
0 & \frac{r_{3}}{r_{1} r_{3}}
\end{array}\right) .
$$

Since $r_{3}=\operatorname{gcd}\left(r_{1},-\alpha_{1} p+\beta_{1} h, \frac{N}{r_{1}}\right)$,

$$
\left(\begin{array}{cc}
\frac{r_{1}}{r_{3}} & \frac{-\alpha_{1} p+\beta_{1} h}{r_{3}} \\
0 & \frac{N}{r_{1} r_{3}}
\end{array}\right)
$$

is integral. Since $\operatorname{det}\left(\mathscr{L}_{1}\right)= \pm 1$, every entry of $\mathscr{M}$ must be a multiple of $r_{3}$. Then $\operatorname{gcd}(l, h, p, n) \geqslant r_{3}>1$; this contradicts with the assumption that $\operatorname{gcd}(l, h, p, n)=1$. Therefore $r_{3}=1$.

Since $r_{3}=\operatorname{gcd}\left(r_{2}, N \beta_{2} / r_{1}\right)$ and $r_{3}=1$, by Lemma 1, there exist integers $\alpha_{3}$ and $\beta_{3}$ such that $\alpha_{3} r_{2}+\beta_{3}\left(N \beta_{2} / r_{1}\right)=1$. Let

$$
\mathscr{L}_{2}=\left(\begin{array}{cc}
\alpha_{3} & \beta_{3} \\
\frac{-N \beta_{2}}{r_{1}} & r_{2}
\end{array}\right)
$$

and let $\mathscr{M}_{3}=\mathscr{L}_{2} \mathscr{M}_{2}$. Then

$$
\mathscr{M}_{3}=\left(\begin{array}{cc}
\alpha_{3} & \beta_{3} \\
\frac{-N \beta_{2}}{r_{1}} & r_{2}
\end{array}\right)\left(\begin{array}{cc}
r_{2} & 0 \\
\frac{N \beta_{2}}{r_{1}} & \frac{N}{r_{2}}
\end{array}\right)=\left(\begin{array}{cc}
1 & \frac{\beta_{3} N}{r_{2}} \\
0 & N
\end{array}\right) .
$$

Let

$$
\mathscr{R}_{2}=\left(\begin{array}{cc}
1 & -\frac{\beta_{3} N}{r_{2}} \\
0 & 1
\end{array}\right) .
$$

and let $\mathscr{M}_{4}=\mathscr{M}_{3} \mathscr{R}_{2}$. Then

$$
\mathscr{M}_{4}=\left(\begin{array}{cc}
1 & \frac{\beta_{3} N}{r_{2}} \\
0 & N
\end{array}\right)\left(\begin{array}{cc}
1 & -\frac{\beta_{3} N}{r_{2}} \\
0 & 1
\end{array}\right)=\left(\begin{array}{ll}
1 & 0 \\
0 & N
\end{array}\right)=\mathscr{S}(\mathscr{M})
$$

From the above, $\mathscr{L}_{2} \mathscr{L}_{1} \mathscr{M} \mathscr{R}_{1} \mathscr{R}_{2}=\mathscr{S}(\mathscr{M})$. Moreover, $\mathscr{L}_{1}, \mathscr{L}_{2}, \mathscr{R}_{1}$ and $\mathscr{R}_{2}$ are unimodular integral matrices. Let $\mathscr{L}=\mathscr{L}_{1} \mathscr{L}_{2}$. Then

$$
\mathscr{L}=\left(\begin{array}{cc}
\alpha_{3} & \beta_{3} \\
\frac{-N \beta_{2}}{r_{1}} & r_{2}
\end{array}\right)\left(\begin{array}{cc}
\alpha_{1} & \beta_{1} \\
\frac{n}{r_{1}} & \frac{l}{r_{1}}
\end{array}\right)=\left(\begin{array}{cc}
\alpha_{3} \alpha_{1}+\frac{\beta_{1} n}{r_{1}} & \alpha_{3} \beta_{1}+\frac{\beta_{3} l}{r_{1} l} \\
\frac{-N \beta_{2} \alpha_{1}}{r_{1}} r_{2} n & \frac{-N \beta_{2} \beta_{1}}{r_{1}} r_{2}
\end{array}\right) .
$$

Using the facts that $N=l h-p n$ and $\alpha_{1} l+\beta_{1}(-n)=r_{1}$ and $\alpha_{2} r_{1}+\beta_{2}\left(-\alpha_{1} p+\beta_{1} h\right)=r_{2}$, we have $\left(-N \beta_{2} \alpha_{1}+r_{2} n\right) / r_{1}=\alpha_{2} n-\beta_{2} h$ and $\left(-N \beta_{2} \beta_{1}+r_{2} l\right) / r_{1}=\alpha_{2} l-\beta_{2} p$. Thus if $S_{1}=\alpha_{2} n-\beta_{2} h(\bmod N)$ and $s_{2}=\alpha_{2} l-\beta_{2} p(\bmod N)$, then $D L\left(N ; s_{1}, s_{2}\right)$ realizes $L$.

It is clear that Steps 1,2 , and 3 can be done in $\mathrm{O}(\log N)$ time by using the Euclidean algorithm. Step 4 can be done in $\mathrm{O}\left((\log N)^{2}\right)$ time by using ALGORITHM-MODIFIEDEUCLIDEAN. Step 5 can be done in $\mathrm{O}(1)$ time. Thus ALGORITHM-COMPUTINGSTEPS takes at most $\mathrm{O}\left((\log N)^{2}\right)$.

The following theorem will be used in the follow-up discussions.
Theorem 6 (Chen and Hwang [4]). Suppose $s_{1}^{\prime}, s_{2}^{\prime}$ realize L-shape( $l, h, n, p$ ). Let $x$ and $y$ be integers such that $s_{2}^{\prime} x-s_{1}^{\prime} y=1$. Then $s_{1}=n x-h y(\bmod N)$ and $s_{2}=l x-$ $p y(\bmod N)$ realize L-shape $(l, h, p, n)$; moreover, $s_{1}, s_{2}$ can be derived from $s_{1}^{\prime}, s_{2}^{\prime}$ in $\mathrm{O}(\log N)$ time.

Theorem 7. If $\operatorname{gcd}(l, n)=1$ or $\operatorname{gcd}(l, p)=1$ or $\operatorname{gcd}(h, p)=1$ or $\operatorname{gcd}(h, n)=1$, then we could use ALGORITHM-COMPUTING-STEPS to find the steps $s_{1}$ and $s_{2}$ of L-shape $(l, h, p, n)$ in only $\mathrm{O}(\log N)$ time.

Proof. There are four cases:
Case 1: $\operatorname{gcd}(l, n)=1$. Then, clearly, $r_{1}=\operatorname{gcd}(l,-n)=1$. Hence $r_{2}=1$ and Step 4 of ALGORITHM-COMPUTING-STEPS takes only $\mathrm{O}(\log N)$ time. Thus ALGORITHM-COMPUTING-STEPS finds the steps $s_{1}$ and $s_{2}$ in only $\mathrm{O}(\log N)$ time.

Case 2: $\operatorname{gcd}(l, p)=1$. By an argument similar to that in Case 1, we could use ALGORITHM-COMPUTING-STEPS to find the steps $s_{1}^{\prime}$ and $s_{2}^{\prime}$ of L-shape $(l, h, n, p)$ in only $\mathrm{O}(\log N)$ time. Then, by Theorem $6, s_{1}, s_{2}$ could be derived from $s_{1}^{\prime}, s_{2}^{\prime}$ in $\mathrm{O}(\log N)$ time.

Case 3: $\operatorname{gcd}(h, p)=1$. By an argument similar to that in Case 1, we could use ALGORITHM-COMPUTING-STEPS to find the steps $s_{1}^{\prime}$ and $s_{2}^{\prime}$ of L-shape $(h, l, n, p)$ in only $\mathrm{O}(\log N)$ time. Since L -shape $(h, l, n, p)$ is the flipping of L -shape $(l, h, p, n)$, $s_{1}=s_{2}^{\prime}$ and $s_{2}=s_{1}^{\prime}$.

Case 4: $\operatorname{gcd}(h, n)=1$. Again, by an argument similar to that in Case 1, we could use ALGORITHM-COMPUTING-STEPS to find the steps $s_{1}^{\prime \prime}$ and $s_{2}^{\prime \prime}$ of L-shape ( $h, l, p, n$ ) in only $\mathrm{O}(\log N)$ time. Then, by Theorem 6 , the steps $s_{1}^{\prime}, s_{2}^{\prime}$ of L -shape $(h, l, n, p)$ could be derived from $s_{1}^{\prime \prime}, s_{2}^{\prime \prime}$ in $\mathrm{O}(\log N)$ time. Since L-shape $(h, l, n, p)$ is the flipping of L-shape $(l, h, p, n), s_{1}=s_{2}^{\prime}$ and $s_{2}=s_{1}^{\prime}$.

We now compare the three existing algorithms for computing the steps of double-loop networks: the Smith normalization method [1,7], the sieve method [3,11], and our algorithm. Both the Smith normalization method and our algorithm take at most $\mathrm{O}\left((\log N)^{2}\right)$ time. In the Smith normalization method, one needs to find nonsingular unimodular integral matrices $\mathscr{L}_{i}, \ldots, \mathscr{L}_{2}, \mathscr{L}_{1}, \mathscr{R}_{1}, \mathscr{R}_{2}, \ldots, \mathscr{R}_{k}$ such that

$$
\mathscr{L}_{i} \cdots \mathscr{L}_{2} \mathscr{L}_{1} \mathscr{M} \mathscr{R}_{1} \mathscr{R}_{2} \cdots \mathscr{R}_{k}=\mathscr{S}(\mathscr{M}) .
$$

Our algorithm is based on the Smith normalization method, but our algorithm does not require any matrix operation; moreover, as could be seen from the proof of Theorem

5, we prove that there exist nonsingular unimodular integral matrices $\mathscr{L}_{2}, \mathscr{L}_{1}, \mathscr{R}_{1}, \mathscr{R}_{2}$ such that

$$
\mathscr{L}_{2} \mathscr{L}_{1} \mathscr{M} \mathscr{R}_{1} \mathscr{R}_{2}=\mathscr{S}(\mathscr{M})
$$

Therefore, our algorithm greatly simplifies the computation of the Smith normalization method.

Both the sieve method and our algorithm are very simple and easy to implement. The sieve method shows that the steps of a double-loop network are of the form

$$
s_{1}=k n+h(\bmod N), \quad s_{2}=k l+p(\bmod N)
$$

and our algorithm shows that the steps of a double-loop network are of the form

$$
s_{1}=\alpha_{2} n-\beta_{2} h(\bmod N), \quad s_{2}=\alpha_{2} l-\beta_{2} p(\bmod N)
$$

The sieve method takes at most $\mathrm{O}\left(P_{\eta(N)} \log N\right)$ time. However, we are unable to predict the value of $P_{\eta(N)}$ and therefore unable to tell which algorithm is more efficient.

It is open whether the steps of a double-loop network can be found in $\mathrm{O}(\log N)$ time. Note that Cheng and Hwang [5] gave an $\mathrm{O}(\log N)$ time algorithm to compute the L-shape of a double-loop network $D L\left(N ; s_{1}, s_{2}\right)$. It is also open whether we can find integers $x$ and $y$ such that $x a+y b=\operatorname{gcd}(a, b)$ and $(y, \operatorname{gcd}(a, b))=1$ in only $\mathrm{O}(\log N)$ time, where $a$ and $b$ are integers, not both zero. If this is true, then ALGORITHM-COMPUTING-STEPS would take only $\mathrm{O}(\log N)$ time and the steps of a double-loop network can be find in $\mathrm{O}(\log N)$ time.

## Acknowledgements

We thank Prof. Frank K. Hwang for many helpful comments. We also thank the referees for many constructive comments that greatly improve the presentation of this paper.
