Received 23 January 1991
Revised 18 July 1991

Abstract

The normalized incomplete beta function \( I_x(a, b) \) is inverted for large values of the parameters \( a \) and \( b \). That is, \( x \)-solutions of the equation

\[
I_x(a, b) = p, \quad p \in [0, 1],
\]

are considered, especially for large values of \( a \) and \( b \). The approximations are obtained by using uniform asymptotic expansions of the incomplete beta function, in which an error function or an incomplete gamma function is the dominant term. The inversion problem is started by inverting this dominant term. Further terms in the expansion are obtained by using standard perturbation methods, which were recently introduced in a paper describing a method for asymptotic inversion of the incomplete gamma functions. Numerical results indicate that for obtaining an accuracy of four correct digits the asymptotic method can already be used for \( a+b \geq 5 \).

Keywords: Incomplete beta function; inversion of beta distribution; asymptotic expansion.

1. Introduction

The incomplete beta function is defined by

\[
I_x(a, b) = \frac{1}{B(a, b)} \int_0^x t^{a-1}(1 - t)^{b-1} \, dt, \quad a > 0, \ b > 0,
\]

where \( B(a, b) \) is Euler's (complete) beta function

\[
B(a, b) = \int_0^1 t^{a-1}(1 - t)^{b-1} \, dt = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}.
\]
We consider the following inversion problem. Let \( p \in [0, 1] \) be given. We are interested in the \( x \)-value that solves the equation

\[
I_x(a, b) = p, \tag{1.3}
\]

where \( a \) and \( b \) are fixed positive numbers. We are especially interested in solving (1.3) for large values of \( a \) and \( b \).

This problem is of great importance in probability theory and mathematical statistics. The incomplete beta function is a standard probability function, with as special cases the (negative) binomial distribution, Student's distribution, and the \( F \) (variance-ratio) distribution. Several approaches are available in the (statistical) literature, where often a first approximation of \( x \), based on asymptotic estimates, is constructed, but this first approximation is not always reliable. Higher approximations may be obtained by numerical inversion techniques, which require evaluation of the incomplete beta function. This may be rather time consuming, especially when \( a \) and \( b \) are large.

In the present method we also use an asymptotic result. The approximation is quite accurate, especially when the parameters \( a \) and \( b \) are large. It follows from numerical results, however, that a three-term asymptotic expansion already gives an accuracy of four significant digits for \( a + b \geq 5 \), uniformly with respect to \( p \in [0, 1] \).

The method of this paper is used earlier in [4] for the asymptotic inversion of the incomplete gamma functions. The present problem is more difficult, of course, since now two large parameters are considered. In fact we consider three asymptotic representations of the incomplete beta function with \( a + b \to \infty \), valid in the following cases:

(i) \( a = b + \beta \), where \( \beta \) stays fixed;
(ii) \( a/b \) and \( b/a \) are bounded away from zero;
(iii) at least one of the parameters \( a, b \) is large.

In the first two cases both parameters are large, in the third case we allow one parameter to be fixed or substantially smaller than the other one. In the first two cases the underlying beta distribution can be approximated by a normal (Gaussian) distribution, and we use an error function as main approximant. In the third case the distribution may be quite skew, and we consider an approximation in terms of the gamma distribution, with an incomplete gamma function as main approximant. It is possible to restrict ourselves to \( a \geq b \), since we have the relation

\[
I_x(a, b) = 1 - I_{1-x}(b, a) \tag{1.4}
\]

This relation is used in the third case, where the only condition is that the sum \( a + b \) should be large.

2. The nearly symmetric case

We write \( b = a + \beta \), where \( \beta \) is fixed. We obtain from (1.1),

\[
I_x(a, a + \beta) = \frac{4^{-a}}{B(a, a + \beta)} \int_0^x \frac{(1-t)^a}{t(1-t)} dt \int_0^x \frac{(1-t)^{a}}{t(1-t)} dt.
\]
We transform this to a standard form with a Gaussian character by writing
\[ \frac{1}{2} \xi^2 = \ln[4t(1-t)], \quad 0 < t < 1, \quad \text{sign}(\xi) = \text{sign}(t - \frac{1}{2}), \]
\[ -\frac{1}{2} \eta^2 = \ln[4x(1-x)], \quad 0 < x < 1, \quad \text{sign}(\eta) = \text{sign}(x - \frac{1}{2}). \]
(2.1)

Therefore
\[ I_x(a, a + \beta) = \frac{4^{-a}}{B(a, a + \beta)} \int_{-\infty}^{\eta} e^{-a \xi^2/2} \left( \frac{1-t}{t(1-t)} \right)^{\beta} \, d\xi. \]

We can write \( t \) as function of \( \xi \):
\[ t = \frac{1}{2} \left[ 1 \pm \sqrt{1 - \exp\left(-\frac{1}{2} \xi^2\right)} \right] = \frac{1}{2} \left[ 1 + \xi \sqrt{1 - \frac{1 - \exp\left(-\frac{1}{2} \xi^2\right)}{\xi^2}} \right], \]
(2.2)

where the second square root is nonnegative for real values of the argument. The same relation holds for \( x \) as function of \( \eta \). It easily follows that
\[ \frac{1}{t(1-t)} \frac{dt}{d\xi} = \frac{-\xi}{1-2t}, \]
and that the following standard form (in the sense of [2]) can be obtained:
\[ I_x(a, a + \beta) = \frac{a}{2\pi} \int_{-\infty}^{\eta} e^{-a \xi^2/2} f(\xi) \, d\xi, \]
(2.3)

with
\[ f(\xi) = \Phi(a) \phi(\xi), \]
(2.4)

where
\[ \Phi(a) = \frac{1}{\sqrt{a}} \frac{\Gamma\left(a + \frac{1}{2} \beta\right) \Gamma\left(a + 1 + \frac{1}{2} \beta\right)}{\Gamma(a) \Gamma(a + \beta)} \quad \text{and} \quad \phi(\xi) = \left[ 2(1-t) \right]^\beta \sqrt{\frac{\frac{1}{2} \xi^2}{1 - \exp\left(-\frac{1}{2} \xi^2\right)}}. \]
(2.5)

This form of \( \Phi(a) \) is obtained by using the duplication formula of the gamma function:
\[ \sqrt{\pi} \Gamma(2z) = 2^{2z-1} \Gamma(z) \Gamma\left(z + \frac{1}{2}\right). \]

From the asymptotic expansion of the ratio of gamma functions (see, for instance, [1, formula 6.1.47]), we obtain
\[ \psi(a) \sim c_0 + c_1 a^{-1} + c_2 a^{-2} + \cdots, \quad a \to \infty, \]
(2.6)

where
\[ c_0 = 1, \quad c_1 = \frac{1}{8} (-2\beta^2 + 2\beta - 1), \quad c_2 = \frac{1}{128} (4\beta^4 + 8\beta^3 - 16\beta^2 + 4\beta + 1). \]

The function \( \phi(\xi) \) is analytic in a strip containing \( \mathbb{R} \); the singularities nearest to the origin occur at \( \pm 2\sqrt{\pi} \exp(\pm \frac{1}{2} i \pi) \). The first coefficients of the Taylor expansion
\[ \phi(\xi) = d_0 + d_1 \xi + d_2 \xi^2 + d_3 \xi^3 + \cdots \]
(2.7)
arc

\[ d_0 = 1, \quad d_1 = -\frac{3}{4} \beta \sqrt{2}, \quad d_2 = \frac{1}{8} (2\beta^2 - 2\beta + 1), \quad d_3 = -\frac{1}{24} \beta \sqrt{2} (\beta^2 - 3\beta + 2), \]
\[ d_4 = \frac{1}{384} (4\beta^4 - 24\beta^3 + 32\beta^2 - 12\beta + 1), \]
\[ d_5 = -\frac{1}{960} \beta \sqrt{2} (\beta^4 - 10\beta^3 + 25\beta^2 - 20\beta + 4). \]

From results in [2] it follows that the standard form (2.3) can be written in the form

\[ I_4(a, a + \beta) = \frac{1}{\sqrt{\pi}} \text{erfc} \left( -\frac{\eta \sqrt{a}}{a} \right) - R_\eta(\eta), \]

where \( \eta \) is defined in (2.1), and \( \text{erfc} \) is the error function defined by

\[ \text{erfc} z = \frac{2}{\sqrt{\pi}} \int_{z}^{\infty} e^{-t^2} dt. \]

We try to solve (1.3) with the above representation of the incomplete beta function. First we solve (1.3) in terms of \( \eta \); afterwards, we determine \( x \) from the inverse relation of the second line in (2.1) (that is, (2.2) with \( t, \zeta \) replaced by \( x, \eta \), respectively). When \( a \) is large, we consider the error function in the equation

\[ I_4(a, a + \beta) = \frac{1}{\sqrt{\pi}} \text{erfc} \left( -\frac{\eta \sqrt{a}}{a} \right) - R_\eta(\eta) = p \]

as the dominant term, and a first approximation \( \eta_0 \) of \( \eta \) is defined by the solution of the equation

\[ \frac{1}{2} \text{erfc} \left( -\frac{\eta_0 \sqrt{a}}{a} \right) = p. \]

The exact solution of (1.3) (in terms of \( \eta \)) is written as

\[ \eta = \eta_0 + \epsilon, \]

and we try to determine \( \epsilon \). It appears that we can expand this quantity in the form

\[ \epsilon \sim \frac{\epsilon_1}{a} + \frac{\epsilon_2}{a^2} + \frac{\epsilon_3}{a^3} + \cdots, \]

as \( a \to \infty \). The coefficients \( \epsilon \) can be expressed in terms of \( \eta_0 \) and \( \beta \).

From (2.3), (2.9) and (2.10) we obtain

\[ \frac{dp}{d\eta_0} = \sqrt{\frac{a}{2\pi}} e^{-a\eta_0^2/2}, \quad \frac{dp}{d\eta} = \sqrt{\frac{a}{2\pi}} f(\eta) e^{-a\eta^2/2}, \]

where \( f \) is given in (2.4). Upon dividing, we obtain

\[ f(\eta) \frac{d\eta}{d\eta_0} = e^{a(\eta^2 - \eta_0^2)/2}. \]

Substitution of (2.11) gives the differential equation

\[ f(\eta_0 + \epsilon) \left(1 + \frac{d\epsilon}{d\eta_0}\right) = e^{a(\eta_0 + \epsilon)/2}. \]

We write \( \eta \) in place of \( \eta_0 \); that is, we try to find \( \epsilon \) as function of \( \eta \) that satisfies (see also (2.4))

\[ \phi(\eta + \epsilon) \Phi(a) \left(1 + \frac{d\epsilon}{d\eta}\right) = e^{a(\eta + \epsilon)/2}. \]

(2.14)
When we have obtained $c$ from this equation (or an approximation), we use it in (2.11) to obtain the final value $\eta$.

The first coefficient $\epsilon_1$ of (2.12) is obtained by comparing dominant terms in (2.14). Since $\Phi(a) = 1 + \phi(a^{-1})$, we obtain

$$\epsilon_1 = \frac{1}{\eta} \ln \phi(\eta). \quad (2.15)$$

This quantity is analytic (as a function of $\eta$) on $\mathbb{R}$; $\phi(\eta)$ is positive on $\mathbb{R}$, and $\phi(0) = 1$. Using (2.7) we obtain for small values of $\eta$,

$$\epsilon_1 = -\frac{1}{2} \beta \sqrt{2} + \frac{1}{8} (1 - 2\beta) \eta - \frac{1}{36} \beta \sqrt{2} \eta^2 - \frac{1}{192} \eta^3 - \frac{1}{3840} \beta \sqrt{2} \eta^4 + \cdots.$$  

Further terms $\epsilon_i$ can be obtained by using more terms in (2.6) and by expanding

$$\phi(\eta + \epsilon) = \phi(\eta) + \epsilon \phi'(\eta) + \frac{1}{2} \epsilon^2 \phi''(\eta) + \cdots,$$

in which (2.12) is substituted to obtain an expansion in powers of $a^{-1}$. In this way we find

$$\epsilon_2 = \frac{1}{2 \eta \phi} (2 \phi \epsilon_1' + 2 \phi' \epsilon_1 + 2 c_1 \phi - \phi \epsilon_1^2), \quad (2.16)$$

$$\epsilon_3 = \frac{1}{8 \eta \phi} (8 \phi \epsilon_2' + 8 \phi' \epsilon_1' \epsilon_1 + 8 c_1 \phi \epsilon_1' + 8 \phi' \epsilon_2 + 4 \phi'' \epsilon_1^2 + 8 c_1 \phi' \epsilon_1 + 8 c_2 \phi - 8 \phi \epsilon_1 \epsilon_2 - 4 \phi \epsilon_2^2 \eta^2 - 4 \phi \epsilon_2 \eta \epsilon_1^2 - \phi \epsilon_1^4). \quad (2.17)$$

The derivatives $\phi'$, $\epsilon'$, etc., are with respect to $\eta$, and all functions are evaluated at $\eta$. For small values of $\eta$ we can use the Taylor series

$$\epsilon_2 = \frac{1}{12} \beta \sqrt{2} (3 \beta - 2) + \frac{1}{128} (20 \beta^2 - 12 \beta + 1) \eta + \frac{1}{768} \beta \sqrt{2} (20 \beta - 1) \eta^2$$

$$+ \frac{1}{4608} (16 \beta^2 + 30 \beta - 15) \eta^3 + \frac{1}{53760} \beta \sqrt{2} (21 \beta + 32) \eta^4$$

$$+ \frac{1}{368640} (-32 \beta^2 + 63) \eta^5 - \frac{1}{23804480} \beta \sqrt{2} (120 \beta + 17) \eta^6 + \cdots,$$

$$\epsilon_3 = \frac{1}{480} \beta \sqrt{2} (-75 \beta^2 + 80 \beta - 16) + \frac{1}{9216} (-1080 \beta^3 + 868 \beta^2 - 90 \beta - 45) \eta$$

$$+ \frac{1}{353760} \beta \sqrt{2} (-1190 \beta^2 + 84 \beta + 373) \eta^2$$

$$+ \frac{1}{368640} (-2240 \beta^3 - 2508 \beta^2 + 2100 \beta - 165) \eta^3 + \cdots.$$  

3. The general error function case

Let us write

$$a = r \sin^2 \theta, \quad b = r \cos^2 \theta, \quad 0 \leq \theta \leq \frac{1}{2} \pi.$$  

Then (1.1) can be written as

$$I_x(a, b) = \frac{1}{B(a, b)} \int_0^x e^{r \sin^2 \theta \ln t + \cos^2 \theta \ln (1-t)}} \frac{df}{t(1-t)}. \quad (3.1)$$
We consider \( r \) as a large parameter, and \( \theta \) bounded away from 0 and \( \frac{1}{2} \pi \). The maximum of the exponential function occurs at \( t = \sin^2 \theta \). Hence, the following transformation brings the exponential part of the integrand into a Gaussian form:

\[
-\frac{1}{2} \xi^2 = \sin^2 \theta \ln \frac{t}{\sin^2 \theta} + \cos^2 \theta \ln \frac{1-t}{\cos^2 \theta},
\]

where the sign of \( \xi \) equals the sign of \( t - \sin^2 \theta \). The same transformation holds for \( x \mapsto \eta \) if \( t \) and \( \xi \) are replaced with \( x \) and \( \eta \), respectively. From (3.2) we obtain,

\[
-\frac{d \xi}{dt} = \frac{\sin^2 \theta - t}{t(1-t)},
\]

and we can write (3.1) in the standard form (cf. (2.3), (2.4))

\[
I_x(a, b) = \sqrt{\frac{r}{2\pi}} \int_{-x}^{r} e^{-r^2/2} f(\xi) d\xi,
\]

with

\[
f(\xi) = \Phi(r) \phi(\xi),
\]

where

\[
\Phi(r) = \frac{\Gamma^*(r)}{\Gamma^*(a) \Gamma^*(b)}, \quad \phi(\xi) = \frac{\xi \sin \theta \cos \theta}{t - \sin^2 \theta}.
\]

The function \( \Gamma^*(z) \) is the slowly varying part of the Euler gamma function. That is,

\[
\Gamma^*(z) = \sqrt{\frac{z}{2\pi}} e^{z^2} \Gamma(z), \quad z > 0,
\]

with

\[
\Gamma^*(z) \sim \sum_{n=0}^{\infty} (-1)^n \gamma_n z^{-n}, \quad \frac{1}{\Gamma^*(z)} \sim \sum_{n=0}^{\infty} \gamma_n z^{-n}, \quad z \to \infty.
\]

The first few \( \gamma_n \) are

\[
\gamma_0 = 1, \quad \gamma_1 = -\frac{1}{12}, \quad \gamma_2 = \frac{1}{288}, \quad \gamma_3 = \frac{139}{51840}.
\]

The analogue of the expansion (2.6) is now in terms of the large parameter \( r \):

\[
\Phi(r) \sim c_0 + c_1 r^{-1} + c_2 r^{-2} + \cdots, \quad r \to \infty,
\]

where

\[
c_0 = 1, \quad c_1 = \frac{\sin^2 \theta \cos^2 \theta - 1}{3 \sin^2 2\theta}, \quad c_2 = \frac{(\sin^2 \theta \cos^2 \theta - 1)^2}{18 \sin^4 2\theta},
\]

\[
c_3 = -\frac{139 (\sin^4 \theta \cos^4 \theta - \cos^6 \theta - \sin^6 \theta) + 15 \sin^4 \theta \cos^4 \theta}{810 \sin^6 2\theta}.
\]

The first coefficients of the Taylor expansion

\[
\phi(\xi) = d_0 + d_1 \xi + d_2 \xi^2 + d_3 \xi^3 + \cdots
\]
To solve (1.3) for large values of \( r \), we use the method of the previous section. We write as in (2.8),
\[
I_x(a, b) = \frac{1}{2} \text{erfc} \left( -\sqrt{\frac{r}{2}} \right) - R_a(\eta),
\]
where the relation between \( x \) and \( \eta \) follows from (3.2). A first approximation \( \eta_0 \) follows from the equation
\[
\frac{1}{2} \text{erfc} \left( -\eta_0 \right) = p,
\]
and the terms \( \epsilon_i \) in the expansion
\[
\epsilon \sim \frac{\epsilon_1}{r} + \frac{\epsilon_2}{r^2} + \frac{\epsilon_3}{r^3} + \cdots
\]
are the same as in (2.15)–(2.17), but with \( \phi, c_1, c_2 \) of the present section. For small values of \( \eta \) we can expand
\[
\epsilon_1 = \frac{2s^2 - 1}{3sc} - \frac{5s^4 - 5s^2 - 1}{36s^2c^2} \eta + \frac{46s^6 - 69s^4 + 21s^2 + 1}{1620s^3c^3} \eta^2
\]
\[
- \frac{-2s^2 - 62s^6 + 31s^8 + 33s^6 + 7}{6480s^4c^4} \eta^3
\]
\[
+ \frac{88s^6 - 52s^2 - 115s^8 + 46s^{10} - 17s^4 + 25}{90720s^5c^5} \eta^4 + \cdots,
\]
\[
\epsilon_2 = -\frac{52s^6 - 78s^4 + 12s^2 + 7}{405s^3c^3} + \frac{2s^2 - 370s^6 + 185s^8 + 183s^4 - 7}{2592s^4c^4} \eta
\]
\[
- \frac{776s^2 + 10240s^6 - 13525s^8 - 533 + 5410s^{10} - 1835s^4}{204120s^5c^5} \eta^2
\]
\[
+ \frac{3747s^2 + 15071s^{12} - 15821s^6 + 45588s^8 - 45213s^{10} - 3372s^4 - 1579}{2099520s^6c^6} \eta^3 + \cdots,
\]
\[
\epsilon_3 = \frac{3704s^{10} - 9260s^8 + 6686s^6 - 769s^4 - 1259s^2 + 449}{102060s^5c^5}
\]
\[
- \frac{750479s^{12} - 151557s^2 - 727469s^6 + 2239932s^8 - 2251437s^{10} + 140052s^4 + 63149}{20995200s^6c^6} \eta
\]
\[
+ \frac{72975s^{14} - 7875s^2 - 2554139s^{12} + 1468795s^8 - 1602610s^6 + 3195183s^{10} + 105222s^4 + 29233}{36741600s^7c^7} \eta^2
\]
\[
+ \cdots,
\]
where \( s = \sin \theta, \ c = \cos \theta. \)

The functions \( \epsilon_i \) are now considered as functions of \( \eta_0 \) (instead of \( \eta \)), and we write
\[
\eta \sim \eta_0 + \frac{\epsilon_1}{r} + \frac{\epsilon_2}{r^2} + \frac{\epsilon_3}{r^3} + \cdots.
\]
This approximation is substituted in the left-hand side of (3.2), and we invert this equation to obtain \( t \), or, equivalently, \( x \).

4. The incomplete gamma function case

In this section we consider the asymptotic condition that the sum \( a + b \) should be large. We concentrate on the case \( a \geq b \). In the other case we can solve (1.3) by using (1.4). From [3, formula (9.16)] it follows that we can write

\[
I_\alpha(y) = Q(b, \eta a) + R_{a,b}(\eta),
\]

where \( \eta \) is given by a mapping \( x \mapsto \eta \), which is defined by

\[
\eta - \mu \ln \eta + A(\mu) = -\ln x - \mu \ln(1 - x),
\]

and

\[
\mu = \frac{b}{a}, \quad A(\mu) = (1 + \mu) \ln(1 + \mu) - \mu.
\]

\( Q \) is the incomplete gamma function defined by

\[
Q(\alpha, z) = \frac{1}{\Gamma(\alpha)} \int_z^\infty t^{\alpha-1} e^{-t} \, dt, \quad \alpha > 0.
\]

Corresponding points in the mapping are

\[
x = 0 \leftrightarrow \eta = \infty, \quad x = \frac{1}{1 + \mu} \leftrightarrow \eta = \mu, \quad x = 1 \leftrightarrow \eta = 0.
\]

From (4.2) it follows that

\[
\frac{dx}{d\eta} = \frac{\eta - \mu}{\eta} \frac{x(1-x)}{(1 + \mu) - 1}.
\]

In [3] an asymptotic expansion of \( R_{a,b}(\eta) \) in (4.1) is derived, which holds for \( a \to \infty \), uniformly with respect to \( x \in [0, 1] \) and \( b \in [0, \infty) \).

We obtain the solution of (1.3) for large values of \( a \), by first determining \( \eta_0 \), the solution of the reduced equation

\[
Q(b, \eta_0 a) = p.
\]

This involves an inversion of the incomplete gamma function, which problem is considered in [4], especially for large values of \( b \). As in the previous sections, the exact solution of (1.3) is written as \( \eta = \eta_0 + \epsilon \), and we expand \( \epsilon \) as in (2.12). We have (cf. (2.13)),

\[
\frac{d\epsilon}{d\eta} = -\frac{\epsilon}{\eta_0 \Gamma(b)} e^{(-\eta_0 + \mu \ln \eta_0)}, \quad \frac{dp}{d\eta} = \frac{1}{B(a, b) x(1-x)} \frac{dx}{d\eta} e^{(-\eta + \mu \ln \eta - A(\mu))}.
\]
Upon dividing these equations and using (4.5), we obtain
\[ f(\eta) \frac{d\eta}{d\eta_0} = \frac{\eta}{\eta_0} e^{\eta - \eta_0 - \mu \ln(\eta/\eta_0)}, \] (4.7)

with \( f(\eta) = \phi(\eta)\Phi(a) \), and
\[ \phi(\eta) = \frac{\eta - \mu}{1 - x(1 + \mu)} \frac{1}{\sqrt{1 + \mu}}, \quad \Phi(a) = \frac{\Gamma^*(a + b)}{\Gamma^*(a)}, \]

where \( \Gamma^* \) is introduced in (3.6). By writing \( \eta = \eta_0 + \epsilon \), and writing \( \eta \) in place of \( \eta_0 \) (for the time being), (4.7) can be written as
\[ \phi(\eta + \epsilon)\Phi(a) \left( 1 + \frac{d\epsilon}{d\eta} \right) = e^{\epsilon - \mu \ln(1 + \epsilon/\eta)}. \] (4.8)

The analogue of the expansion (2.6) has coefficients
\[ c_0 = 1, \quad c_1 = -\frac{\mu}{12(1 + \mu)}, \quad c_2 = \frac{\mu^2}{288(1 + \mu)^2}, \quad c_3 = \frac{\mu(432 + 432\mu + 139\mu^2)}{51840(1 + \mu)^3}. \]

The analogue of (2.7) reads
\[ \phi(\eta) = d_0 + d_1(\eta - \mu) + d_2(\eta - \mu)^2 + \cdots, \]
with coefficients
\[ d_0 = 1, \quad d_1 = \frac{w + 2}{3(w + 1)w}, \quad d_2 = \frac{1}{12w^2}, \quad d_3 = \frac{8w^3 + 9w^2 - 9w - 8}{540w(w + 1)^3}, \]
\[ d_4 = \frac{15w^4 - 68w^3 - 182w^2 - 68w + 15}{12960w^4(w + 1)^4}, \]
\[ d_5 = \frac{32w^5 + 265w^4 + 253w^3 - 253w^2 - 265w - 32}{90720w^5(w + 1)^5}, \]

where
\[ w = \sqrt{1 + \mu}. \] (4.9)

Substituting
\[ \epsilon \sim \frac{\epsilon_1}{a} + \frac{\epsilon_2}{a^2} + \frac{\epsilon_3}{a^3} + \cdots \] (4.10)

into (4.8), we find the first coefficient
\[ \epsilon_1 = \frac{\ln \phi(\eta)}{1 - \mu/\eta}, \]
a regular function at \( \eta = \mu \), as follows from the expansion of \( \phi(\eta) \) at this point. The next terms are

\[
\epsilon_2 = \frac{1}{2 \phi \eta (\eta - \mu)} \left( 2 \phi \epsilon_1 \eta^2 + 2 \phi' \epsilon_1 \eta^2 + 2 c_1 \phi \eta^2 - \phi \mu \epsilon_1^2 - 2 \epsilon_1 \phi \eta \right),
\]

\[
\epsilon_3 = \frac{1}{6 \eta^2 \phi^2 (\eta - \mu)^2} \left( -3 \phi^2 \epsilon_1^2 \eta^4 - 6 c_1 \phi^2 \eta^2 - 6 \phi^2 \epsilon_1 \eta^3 + 6 \eta^4 c_2 \phi^2 + 6 \epsilon_1 \phi^2 \eta^3
\]

\[
= -3 \phi^2 \epsilon_1^2 \eta^4 - 6 c_1 \phi^2 \eta^2 + 6 \eta^4 \phi^2 \epsilon_1 + 2 \mu \epsilon_1^2 \eta \phi^2
\]

\[
- 6 \epsilon_1 \phi^2 \eta^2 \mu \epsilon_1' - 9 \epsilon_1^2 \phi \eta^2 \mu \phi' - 6 \epsilon_1 \phi^2 \eta^2 \mu c_1 + 6 \epsilon_1^2 \phi^2 \eta \mu
\]

\[
- 12 \phi' \epsilon_1 \eta^3 \phi + \mu^2 \phi^2 \epsilon_1^3 + 6 \eta^4 \epsilon_2 \phi^2 + 3 \eta^3 \mu c_1 \phi^2 - 6 \eta^3 \mu c_2 \phi^2
\]

\[
+ 3 \eta^3 \mu \epsilon_1^2 \phi^2 - 6 \eta^3 \mu \epsilon_2 \phi^2 + 6 c_1 \eta^4 \phi' \phi + 6 \epsilon_1 \eta^4 \phi' \phi
\]

\[
+ 3 \eta^4 \phi \epsilon_1^2 - 3 \eta^3 \mu \phi^2 \epsilon_1^2 + 3 \eta^3 \mu \phi^2 \epsilon_1^2,
\]

where the derivatives are with respect to \( \eta \). For small values of \( |\eta - \mu| \) we can expand

\[
\epsilon_1 = \frac{(w + 2)(w - 1)}{3w} + \frac{w^3 + 9w^2 + 21w + 5}{36w^2(w + 1)} (\eta - \mu)
\]

\[
- \frac{w^4 - 13w^3 + 69w^2 + 167w + 46}{1620(w + 1)^2 w^3} (\eta - \mu)^2
\]

\[
- \frac{7w^5 + 21w^4 + 70w^3 + 26w^2 - 93w - 31}{6480(w + 1)^3 w^4} (\eta - \mu)^3
\]

\[
- \frac{75w^6 + 202w^5 + 188w^4 - 888w^3 - 1345w^2 + 118w + 138}{272160(w + 1)^4 w^5} (\eta - \mu)^4 + \cdots,
\]

\[
\epsilon_2 = \frac{(28w^4 + 131w^3 + 402w^2 + 581w + 208)(w - 1)}{1620(w + 1)^4 w^3}
\]

\[
- \frac{35w^6 - 154w^5 - 623w^4 - 1636w^3 - 8w^2 + 3514w - 925}{12960(w + 1)^3 w^4} (\eta - \mu)
\]

\[
- \frac{2132w^7 + 7915w^6 + 16821w^5 + 35066w^4 + 87490w^3 + 141183w^2 + 95993w + 21640}{816480w^5(w + 1)^3} (\eta - \mu)^2
\]

\[
- \frac{11053w^8 + 53308w^7 + 117010w^6 + 163924w^5 + 116188w^4 - 258428w^3 - 677042w^2 - 481940w - 105497}{14696640(w + 1)^4 w^6}
\]

\[
\times (\eta - \mu)^3 + \cdots.
\]

\[
\epsilon_3 = - \left[ (3592w^7 + 8375w^6 - 1323w^5 - 29198w^4 - 89578w^3 - 154413w^2
\]

\[
- 116063w - 29632)(w - 1) \right] / \left[ 816480w^5(w + 1)^3 \right]
\]

\[
- (442043w^9 + 2054169w^8 + 3803094w^7 + 3470754w^6 + 2141568w^5
\]
where $w$ is given by (4.9).

Considering the functions $\epsilon$ as functions of $\eta_0$, we obtain using (4.10),

$$\eta \approx \eta_0 + \frac{\epsilon_1}{a} + \frac{\epsilon_2}{a^2} + \frac{\epsilon_3}{a^3} + \cdots,$$

which is substituted in the left-hand side of (4.2). Solving for $x$, we finally obtain the desired approximation of the solution of (1.3).

In this section, the functions $\Phi(a)$, $\phi(\eta)$, $\epsilon$ have expansions with coefficients $c_i$, $d_i$, $e_i$ in which the parameter $\mu = b/a$ may assume any value in $[0, \infty)$. This aspect demonstrates the uniform character (with respect to $\mu$) of the present approach. In Section 2 large values of $\beta$ are not allowed, and in Section 3 the value of $\beta$ should be bounded away from 0 and $\frac{1}{2}\pi$. Of course, the transformations and expansions of this section are more complicated than those in the previous sections. Moreover, to start the inversion procedure, first (4.6) including an incomplete gamma function should be solved, whereas in the foregoing cases only an error function has to be inverted. See (2.10) and (3.9).

5. Numerical aspects

In numerical applications one needs the inversion of the mappings given in (2.1), (3.2) and (4.2). Only (2.1) can be inverted directly, as shown in (2.2). For small values of $|\xi|$ we have

$$t = \frac{1}{2} + \frac{1}{4} \sqrt{2} \zeta - \frac{1}{8} \sqrt{2} \zeta^3 + \frac{5}{16} \sqrt{2} \zeta^5 + \cdots.$$

The inversion of (4.2) can be based on that of (3.2), with other parameters. We give some details on the inversion of (3.2).

For small values of $|\xi|$ we have

$$t = s^2 + sc\zeta + \frac{1}{3} (1 - 2s^2) \zeta^2 + \frac{13s^4 - 13s^2 + 1}{36sc} \zeta^3 + \frac{46s^6 - 69s^4 + 21s^2 + 1}{270s^2c^2} \zeta^4 + \cdots,$$

where $s = \sin \theta$, $c = \cos \theta$. For larger values of $|\xi|$, with $\zeta < 0$, we rewrite (3.2) in the form

$$t (1 - t)^{a} = u, \quad \alpha = \cot^2 \theta, \quad u = \exp \left( -\frac{1}{2} \zeta^2 + s^2 \ln s^2 + c^2 \ln c^2 \right),$$

and for small values of $u$ we expand

$$t = u + au + \frac{3a(3a + 1)}{3!} u^3 + \frac{4a(4a + 1)(4a + 2)}{4!} u^4 + \frac{5a(5a + 1)(5a + 2)(5a + 3)}{5!} u^5 + \cdots.$$

A similar approach is possible for positive values of $\mu$, giving an expansion for $t$ near unity. The approximations obtained in this way may be used for starting a Newton–Raphson method for obtaining more accurate values of $t$.

We have tested the inversion process of the incomplete beta function for several values of the parameters. We describe the testing for the method of Section 2. After obtaining the first approximation $\eta_0$ by inverting (2.10), we computed the values of $\epsilon_1, \epsilon_2, \epsilon_3$, defined in (2.15)–(2.17) (with $\eta$ replaced with $\eta_0$). The coefficient $\epsilon_3$ is included only when $\eta_0$ is small enough for using the Taylor series given in Section 2. Next, (2.11) gives the final approximation
of \( \eta \), which is used in the second line in (2.1), to obtain the approximation of \( x \). Finally we verified (1.3) by computing the incomplete beta function with this value \( x \). We used the continued fraction given in [1, formula 26.5.8].

In Tables 5.1–5.3 we show the relative errors \(|(I_x(a, b) - p)/p|\), where \( x \) is obtained by the asymptotic inversion methods of Sections 2–4. As is expected, it follows that the larger values of \( \beta \) give less accuracy in the results in Table 5.1. The same holds for smaller values of \( \theta \) in Table 5.2. From Table 5.3 it follows that the results are not influenced by large or small values of \( \mu \). This shows the uniform character of the method of Section 4. In fact, this method can be used in extreme situations: the ratio \( a/b \) may be very small and very large, and \( p \) may assume values quite close to zero or to unity.
