Received January 7, 1999

We consider a general second-order hyperbolic equation defined on an open bounded domain \( \Omega \subset \mathbb{R}^n \) with variable coefficients in both the elliptic principal part and in the first-order terms as well. At first, no boundary conditions (B.C.) are imposed. Our main result (Theorem 3.5) is a reconstruction, or inverse, estimate for solutions \( w \): under checkable conditions on the coefficients of the principal part, the \( H^1(\Omega) \times L^2(\Omega) \)-energy at time \( t = T \), or at time \( t = 0 \), is dominated by the \( L^2(\Gamma) \)-norms of the boundary traces \( \partial w / \partial n \) and \( w \), modulo an interior lower-order term. Once homogeneous B.C. are imposed, our results yield—a uniqueness theorem, needed to absorb the lower-order term—continuous observability estimates for both the Dirichlet and Neumann case, with an explicit, sharp observability time; hence, by duality, exact controllability results. Moreover, no artificial geometrical conditions are imposed on the controlled part of the boundary in the Neumann case. In contrast with existing literature, the first step of our method employs a Riemann geometry approach to reduce the original variable coefficient principal part problem in \( \Omega \subset \mathbb{R}^n \) to a problem on an appropriate Riemann manifold (determined by the coefficients of the principal part), where the principal part is the Laplacian. In our second step, we employ explicit Carleman estimates at the differential level to take care of the variable first-order (energy level) terms. In our third step, we employ micro-local analysis yielding a sharp trace estimate, to remove artificial geometrical conditions on the controlled part of the boundary, in the Neumann case.

1. INTRODUCTION. DUAL PROBLEM: CONTINUOUS OBSERVABILITY INEQUALITIES. LITERATURE

Standing Assumptions

(H.1): Let $\Omega \subset \mathbb{R}^n$ be a bounded, open domain with boundary $\Gamma = \partial \Omega$ of class $C^2$. Let $\Gamma_0$ and $\Gamma_1$ be open disjoint subsets of $\Gamma$ with $\Gamma = \Gamma_0 \cup \Gamma_1$.

Let

$$\mathcal{A}w = -\sum_{i,j=1}^{n} \frac{\partial}{\partial x_i} \left( a_{ij}(x) \frac{\partial w}{\partial x_j} \right), \quad x = [x_1, \ldots, x_n]$$

be a second-order differential operator, with real coefficients $a_{ij} = a_{ji}$ of class $C^1$, see Remark 2.1 below, satisfying the uniform ellipticity condition

$$\sum_{i,j=1}^{n} a_{ij}(x) \xi_i \xi_j \geq a \sum_{i=1}^{n} \xi_i^2, \quad x \in \Omega,$$

for some positive constant $a > 0$. Assume further that

$$\sum_{i,j=1}^{n} a_{ij}(x) \xi_i \xi_j > 0, \quad \forall x \in \mathbb{R}^n, \quad \xi = (\xi_1, \xi_2, \ldots, \xi_n) \in \mathbb{R}^n, \quad \xi \neq 0.$$

(H.2): Let $F_t(w)$ be a linear, first-order differential operator in all variables $\{t, x_1, \ldots, x_n\}$ on $w$ with $L_\infty(Q)$-coefficients, thus satisfying the following pointwise estimate: there exists a constant $C_T > 0$ such that

$$|F_t(w)|^2 \leq C_T \left[ w_t^2 + |\nabla w|^2 + w^2 \right], \quad \forall t, x \in Q,$$

where $Q = (0, T) \times \Omega$ and $w(t, x) \in C^1(Q)$. Let $(0, T) \times \Gamma_i = \Sigma_i, i = 0, 1$; $(0, T) \times \Gamma = \Sigma$. (Lower regularity than $L_\infty$ can be assumed for the zero-order term, depending on the dimension $n$ via Sobolev embedding, but we shall not insist on this detail.)
**Dirichlet Control**

We consider the Dirichlet mixed second-order hyperbolic problem in the unknown \( w(t, x) \) and its dual homogeneous problem in \( \psi(t, x) \),

\[
\begin{align*}
    w_t + \mathcal{A}w &= F_1(w) & \text{in } Q; \\
    w(0, \cdot) &= w_0, \quad w_t(0, \cdot) = w_1 & \text{in } \Omega; \\
    w|_{\Sigma_2} &= 0 & \text{in } \Sigma_0; \\
    w|_{\Sigma_1} &= u & \text{in } \Sigma_1; \\
    \psi_t + \mathcal{A}\psi &= F(\psi) & \text{in } Q; \\
    \psi(T, \cdot) = \psi_0, \quad \psi_t(T, \cdot) = \psi_1 & \text{in } \Omega; \\
    \psi|_{\Sigma} &= 0 & \text{in } \Sigma,
\end{align*}
\]  

with control function \( u \in L_2(0, T; L_2(\Gamma_1)) \) in the Dirichlet B.C., where \( F(\psi) \) is a suitable first-order differential operator, depending on the original operator \( F_1 \), and satisfying the same pointwise bound such as (1.3) for \( F_1 \).

**Continuous Observability Inequality in the Dirichlet Case**

As our first goal, we seek to establish under a suitable additional assumption—the following a priori inequality for the homogeneous Dirichlet \( \psi \)-problem (1.4): there exists a constant \( T_0 > 0 \), depending upon the triple \( \{ \Omega, \Gamma_0, \Gamma_1 \} \) and the coefficients \( a_{ij} \), such that for all \( T > T_0 \), there is a constant \( c_T > 0 \) for which

\[
\int_0^T \int_{\Gamma_1} \left( \frac{\partial \psi}{\partial \nu_\Omega} \right)^2 d\Sigma_1 \geq c_T \| (\psi_0, \psi_1) \|_{L^2(\Omega) \times L^2(\Omega)}^2. \tag{1.5}
\]

In (1.5), \( \partial \psi / \partial \nu_\Omega = \sum_{i,j=1}^d a_{ij}(\partial \psi / \partial x_i) \nu_j \) is the co-normal derivative, where \( \nu = [\nu_1, \ldots, \nu_d] \) is the unit outward normal on \( \Gamma \). Equation (1.5) is the continuous observability inequality for the \( \psi \)-problem (1.4) in the established terminology of [2]. As is well known, e.g., [10, 13, 27], inequality (1.5) for the \( \psi \)-problem (1.4) is, by duality or transposition, equivalent to the exact controllability property of the nonhomogeneous \( w \)-problem (1.4) at time \( T \), on the space \( L_2(\Omega) \times H^{-1}(\Omega) \), within the class of \( L_2(0, T; L_2(\Gamma_1)) \)-controls; in other words, such exact controllability is the property that the map \( L_T \):

\[
\{ u, w_0 = 0, w_1 = 0 \} \\
\rightarrow L_T u \equiv \{ w(T, \cdot), w_t(T, \cdot) \} \text{ is surjective from } L_2(0, T; L_2(\Gamma_1)) \text{ onto } L_2(\Omega) \times H^{-1}(\Omega), \tag{1.6a}
\]
with \( \{w(T, \cdot), w_t(T, \cdot)\} \) solution of the \( w \)-problem (1.4) at \( t = T \); while inequality (1.5) is a restatement [27] of the following standard [24, p. 235] inequality from below of the corresponding adjoint:

\[
\|L_T^* z\|_{L^2(0, T; L^2(\Gamma_1))} \geq c_T \|z\|_{L^2(\Omega) \times H^{-1}(\Omega)},
\]

(1.6b)

which is well known to be equivalent to the surjectivity property (1.6a).

**Remark 1.1.** The converse (trace regularity) of inequality (1.5) always holds true, for any \( T > 0 \) [12, 11, 19].

**Neumann Control**

Here we let \( \Gamma_0 \neq \emptyset, \Gamma_0 \cap \Gamma_1 = \emptyset \), and consider the Neumann mixed second-order hyperbolic problem in the unknown \( w(t, x) \) and its dual homogeneous version in \( \psi(t, x) \):

\[
\begin{align*}
w_{tt} + \mathcal{A} w &= F(w); & \psi_{tt} + \mathcal{A} \psi &= F(\psi) \quad \text{in } Q; \\
w(0, \cdot) &= w_0, & \psi(T, \cdot) &= \psi_0, \\
\psi|_{\Sigma_0} &= 0, & \psi|_{\Sigma_1} &= 0 \quad \text{in } \Sigma_0; \\
\partial w \big/ \partial n|_{\Sigma_1} &= u; & \left[ \partial \psi \big/ \partial n + \beta \psi \right] |_{\Sigma_1} &= 0 \quad \text{in } \Sigma_1,
\end{align*}
\]

(1.7)

with control function \( u \in L^2(0, T; L^2(\Gamma_1)) = L^2(\Sigma_1) \) in the Neumann B.C., where \( F \) is a suitable first-order differential operator depending on \( F_1 \), and satisfying the same pointwise estimate such as (1.3) for \( F_1 \), and \( \beta \) is a suitable function, depending on \( F_1 \).

**Continuous Observability Inequality in the Neumann Case**

As our second goal, we seek to establish—under a suitable additional assumption—the following a priori inequality for the homogeneous Neumann \( \psi \)-problem (1.7): there exists a constant \( T_0 > 0 \), depending upon the triple \( (\Omega, \Gamma_0, \Gamma_1) \) and the coefficients \( a_{ij} \), such that for all \( T > T_0 \), there is a constant \( c_T > 0 \) for which

\[
\int_0^T \int_{\Gamma_1} \psi_t^2 \, d\Sigma_1 \geq c_T \left\| \left\{ \psi_0, \psi_1 \right\} \right\|_{H^1_0(\Omega) \times L^2(\Omega)},
\]

(1.8)

where \( H^1_0(\Omega) = \{ f \in H^1(\Omega): f|_{\Gamma_0} = 0 \} \), whenever the left-hand side is finite. This is the **continuous observability inequality** for the \( \psi \)-problem (1.7) [2]. Again, by duality or transposition, inequality (1.8) is equivalent (see,
e.g., [10, 14, 15]) to the exact controllability property of the nonhomoge-
neous $w$-problem (1.7) at time $T$, on the space $H^1_{1_0}(\Omega) \times L_2(\Omega)$, within the
class of $L_2(0, T; L_2(\Gamma_1))$-controls; in other words, such exact controllability
is the property that the map $L_T$:

$$
\{u, w_0 = 0, w_1 = 0\}
\rightarrow L_T u = \{w(T, \cdot), w_1(T, \cdot)\}
$$

is surjective from

$$
L_2(0, T; L_2(\Gamma_1)) \text{ onto } H^1_{1_0} \times L_2(\Omega), \quad (1.9a)
$$

with $\{w(T, \cdot), w_1(T, \cdot)\}$ solution of the $w$-problem (1.7) at $t = T$, while
inequality (1.8) is a restatement [14] of the following standard [24, p. 235]
inequality from below of the corresponding adjoint:

$$
\|L^*_T z\|_{L_2(0, T; L_2(\Gamma_1))} \geq c_T \|z\|_{H^1_{1_0} \times L_2(\Omega)}, \quad (1.9b)
$$

which is well known to be equivalent to the surjectivity property (1.9a) [14].

**Remark** 1.2. The converse of inequality (1.8) is false for dim $\Omega \geq 2,$
and is true for dim $\Omega = 1$ [16], for any $T > 0.$

**Literature**

Our results are more general than just continuous observability esti-
mates, or—by duality—exact controllability statements. The latter are
generally obtained in the literature through the former [2], on the basis of
the standard functional analysis result [24, p. 235] quoted before. One
exception is the approach pursued by Littman, who seeks exact controlla-
bility results directly, without passing through continuous observability
inequalities [20–22].

A detailed analysis of the various methods used in the literature to
establish continuous observability inequalities, such as (1.5) and (1.8),
along with a description of their virtues and shortcomings, was already
given in our previous announcement [18] of the present paper. They are:

(i) (By now classical) differential multipliers—$h \cdot \nabla \psi, \psi \text{ div } h$—
used after [11], in [13, 5, 14, 19, 27] in 1986, where $h(x)$ is a coercive vector
field. They have been successful in proving the continuous observability
inequalities (1.5) and (1.8) in the case where $\mathcal{A} = -\Delta$ (or in the case of
constant coefficients $a_{ij}$ of the principal part). However, these original
differential multipliers tolerate additional terms only below the energy
level; i.e., a zero-order operator $F$ is fine, but a truly first-order operator $F$
causes the method to fail.
(ii) Pseudodifferential multipliers, micro-local analysis, propagation of singularities initiated in [20] and culminated into the general treatment in [1]. However, it is not an easy matter to verify in applications and examples the (sharp) sufficient condition that all rays of geometric optics hit the effective controlled part $\Sigma_1 = (0, T] \times \Gamma_1$ of the lateral boundary $\Sigma$ of the cylinder $Q$ at a nondiffractive point. Moreover, the method uses $C^\infty$ data and $\Gamma_1$, at least at present. Extension to other nonhyperbolic models, such as plate-like problems, seems a serious issue.

(iii) General pseudodifferential multipliers derived from pseudoconvex functions [6] for general evolution equations [25]. These techniques with pseudodifferential Carleman multipliers proposed in [25], which in prior literature [6] were applied to solutions with compact support (thereby not accounting for boundary traces which are instead critical for continuous observability inequalities) are unifying across several evolution equations. However, they require the existence of a pseudoconvex function, a property which essentially can be verified mostly if not exclusively in the case of constant coefficients $a_{ij}$ of the principal part $A$. Moreover, at least in [25], the control is taken to be active on the entire boundary $\Gamma$.

(iv) Subsequent specific, corresponding differential multipliers versions (much more flexible than classical differential multipliers in (i)), tuned to second-order hyperbolic equations [17, 8, 3]. In the specific concrete analysis of differential Carleman multipliers tuned to second-order hyperbolic equations, the drawback of the existence of pseudoconvex function remains, of course, while now a more detailed analysis—this time at the differential rather than the pseudodifferential level—allows the control to act on a suitable part of the boundary. These differential Carleman multipliers can be viewed as a nontrivial generalization of the original differential multipliers $h \cdot \nabla, \psi \, \text{div} \, h$ in (i), over which they possess an added flexibility via the parameter $\tau$ below, which allows to handle also those first-order terms $F$ as in (1.3), that original multipliers could not deal with.

The general, technical, sharp approach in [1] which follows the dynamics along bi-characteristics—the carriers of energy—did not seal the problem. Other approaches, mentioned above, made connections with other ideas in the P.D.E.’s area, such as pseudoconvex functions and Carleman estimates, and injected new enlightenment into the continuous observability inequalities. Even this further development does not seal the problem, and the infusion of other ideas is possible. In this scenario, recently Riemann geometric methods were introduced and combined with classical differential multipliers as in (i), to establish continuous observability inequalities, such as (1.5) and (1.8) [28]. This method has the virtue of allowing variable coefficients $a_{ij}(x)$ of the principal part $A$, subject to certain verifiable
assumptions. However, in its original form [28], this approach also cannot handle genuine first-order energy level terms $F$. The reason will be explained in Remark 4.2.1 below. Moreover, the treatment in [28] required unnecessary geometrical conditions.

**Contribution of the Present Paper**

In this paper, we present a successful combination of three key ingredients which allow to establish the validity of the continuous observability inequalities (1.5) and (1.8) in the case of (a) variable coefficients $a_{ij}(x)$ of the principal part $a$, subject to verifiable conditions, (b) genuine first-order, energy level terms $F$, and (c) with no artificial geometric conditions in the Neumann case. These three ingredients are (1) the Riemann geometric approach of [28], (2) the Carleman differential multipliers used in [17], which now replace the original classical differential multipliers of [28], expressed though in the Riemann metric, (3) the pseudodifferential approach in [15] which led to an $L_2$-estimate of the tangential derivative (gradient) of the solution $w$ in terms of $L_2$-boundary estimates of $w_t$ and $\partial w/\partial n$, modulo lower-order terms; see Lemma 6.2 below.

It is ingredient (2) that permits the addition of a bona fide first-order operator $F_1$ as in (1.3) to the result of [28]. Further, it is ingredient (3) that permits the elimination of geometrical conditions present in [28] in the Neumann case.

The present approach provides the optimal time for the validity of the continuous observability inequalities (1.5) and (1.8) as is the case with pseudoconvex functions.

Our new main differential multiplier is (see (4.2.2) below)

$$e^{\tau \phi(x,t)}[\langle \nabla_g \phi, \nabla_g w \rangle_g - \phi w_t]$$

in the Riemann metric $(\mathbb{R}^n, g)$ below, where $\phi$ is the pseudoconvex function defined in (3.6a) below. Additional multipliers in the proof below are

$$w \left[ \text{div}_g e^{\tau \phi} \nabla_g \phi - \frac{d}{dt} (e^{\tau \phi} \phi) \right]; we^{\tau \phi},$$

see Lemma 4.2.2 with $m = \mu$ defined in (4.2.14). In the present paper, the inverse/observability estimates are given at the $H^1(\Omega) \times L_2(\Omega)$-level. In a companion paper [18a], we provide a global inverse/observability estimate at the $L_2(\Omega) \times H^1(\Omega)$-level also in the variable coefficient case: here the pseudo-differential/micro-local analysis approach of [15], which required $a = -\Delta$ and $F_1$ a zero order operator in just one step, is
integrated with the Riemann geometric approach for such step, thus extending the estimate of [15].

2. RIEMANNIAN METRIC GENERATED BY THE PRINCIPAL PART $\mathscr{A}$

Recalling the coefficients $a_{ij} = a_{ji}$ of $\mathscr{A}$, let $A(x)$ and $G(x)$ be, respectively, the coefficient matrix and its inverse

$$
A(x) = (a_{ij}(x)); \quad G(x) = [A(x)]^{-1} = (g_{ij}(x)),
$$

(2.1)
i, j = 1, \ldots, n; \quad x \in \mathbb{R}^n.

Both $A(x)$ and $G(x)$ are $n \times n$ matrices. $A(x)$ is positive definite for any $x \in \mathbb{R}^n$ by assumption (1.2b).

**Riemannian Metric**

Let $\mathbb{R}^n$ have the usual topology and $x = [x_1, x_2, \ldots, x_n]$ be the natural coordinate system. For each $x \in \mathbb{R}^n$, define the inner product and the norm on the tangent space $\mathbb{R}_x^n = \mathbb{R}^n$

$$
g(X, Y) = \langle X, Y \rangle_g = \sum_{ij=1}^{n} g_{ij}(x) \alpha_i \beta_j,
$$

(2.2)

$$
|X|_g = \langle X, X \rangle_g^{1/2}, \quad \forall X = \sum_{i=1}^{n} \alpha_i \frac{\partial}{\partial x_i}, \quad Y = \sum_{i=1}^{n} \beta_i \frac{\partial}{\partial x_i} \in \mathbb{R}_x^n. \tag{2.3}
$$

It is easily checked from (1.2b) that $(\mathbb{R}^n, g)$ is a Riemannian manifold with the Riemannian metric $g$. We shall denote $g = \sum_{ij=1}^{n} g_{ij} \, dx_i \, dx_j$. (If $A(x) = I$, i.e., $\mathscr{A} = -\Delta$, then $G(x) = I$, and $g$ is the Euclidean $\mathbb{R}^n$-metric.)

**Euclidean Metric**

For each $x \in \mathbb{R}^n$, denote by

$$
X \cdot Y = \sum_{i=1}^{n} \alpha_i \beta_i, \quad |X|_0 = (X \cdot Y)^{1/2},
$$

(2.4)

$$
\forall X = \sum_{i=1}^{n} \alpha_i \frac{\partial}{\partial x_i}, \quad Y = \sum_{i=1}^{n} \beta_i \frac{\partial}{\partial x_i} \in \mathbb{R}_x^n,
$$

the Euclidean metric on $\mathbb{R}^n$. For $x \in \mathbb{R}^n$, and with reference to (2.1), set

$$
A(x) X = \sum_{i=1}^{n} \left( \sum_{j=1}^{n} a_{ij}(x) \alpha_j \right) \frac{\partial}{\partial x_i}, \quad \forall X = \sum_{i=1}^{n} \alpha_i \frac{\partial}{\partial x_i} \in \mathbb{R}_x^n. \tag{2.5}
$$
Thus, recalling the co-normal derivative defined below (1.5), we have

\[
\frac{\partial w}{\partial \nu_d} = \sum_{i=1}^{n} \left( \sum_{j=1}^{n} a_{ij}(x) \frac{\partial w}{\partial x_j} \right) \nu_i = (A(x)\nabla_0 w) \cdot \nu. \tag{2.6}
\]

In (2.6), and hereafter, we denote by a sub “0” entities in the Euclidean metric. Thus, for \( f \in C^2(\Omega) \) and \( X = \sum_{i=1}^{n} a_i(x)(\partial / \partial x_i) \) a vector field on \( \mathbb{R}^n \),

\[
\nabla_0 f = \sum_{i=1}^{n} \frac{\partial f}{\partial x_i} \text{ and } \text{div}_0(X) = \sum_{i=1}^{n} \frac{\partial a_i(x)}{\partial x_i} \tag{2.7}
\]

denote gradient of \( f \) and divergence of \( X \) in the Euclidean metric.

**Further Relationships**

If \( f \in C^2(\Omega) \), we define the gradient \( \nabla_0 f \) of \( f \) in the Riemannian metric \( g \), via the Riesz representation theorem, by

\[
X(f) = \langle \nabla_0 f, X \rangle_g, \tag{2.8}
\]

where \( X \) is any vector field on the manifold \((\mathbb{R}^n, g)\). The following lemma provides further relationships [28, Lem. 2.1].

**Lemma 2.1.** Let \( x = [x_1, x_2, \ldots, x_n] \) be the natural coordinate system in \( \mathbb{R}^n \). Let \( f, h \in C^2(\Omega) \). Finally, let \( H, X \) be vector fields. Then, with reference to the above notation, we have

(a)

\[
\langle H(x), A(x)X(x) \rangle_g = H(x) \cdot X(x), \quad x \in \mathbb{R}^n; \tag{2.9}
\]

(b)

\[
\nabla_0 f(x) = \sum_{i=1}^{n} \left( \sum_{j=1}^{n} a_{ij}(x) \frac{\partial f}{\partial x_j} \right) \frac{\partial}{\partial x_i} = A(x)\nabla_0 f, \quad x \in \mathbb{R}^n; \tag{2.10}
\]

(c) if \( X = \sum_{i=1}^{n} \xi_i(\partial / \partial x_i) \), then by (2.8) and (2.10),

\[
X(f) = \langle \nabla_0 f, X \rangle_g = \langle A\nabla_0 f, X \rangle_g = \nabla_0 f \cdot X = \sum_{i=1}^{n} \xi_i \frac{\partial f}{\partial x_i}; \tag{2.11}
\]

(d) by (2.6) and (2.10),

\[
\frac{\partial w}{\partial \nu_d} = (A(x)\nabla_0 w) \cdot \nu = \nabla_0 w \cdot \nu; \tag{2.12}
\]
(e) by (2.8), (2.10), (2.9),
\[
\langle \nabla_g f, \nabla_g h \rangle_g = \nabla_g f(h) = \langle A(x) \nabla_0 f, \nabla_0 h \rangle_g \\
= \nabla_0 f \cdot \nabla_0 h = \nabla_0 f \cdot A(x) \nabla_0 h, \quad x \in \mathbb{R}^n;
\]
(2.13)

(f) if \( H \) is a vector field in \( (\mathbb{R}^n, g) \) (see, e.g., (2.16) below),
\[
\langle \nabla_g f, \nabla_g (H(f)) \rangle_g = DH(\nabla_g f, \nabla_g f) + \frac{1}{2} \text{div}_0(\nabla_g f^2 H)(x) \\
- \frac{1}{2} \nabla_g f^2(x) \text{div}_0(H)(x), \quad x \in \mathbb{R}^n,
\]
(2.14)
where \( DH \) is the covariant differential discussed below;

(g) by (1.1), (2.7), (2.10),
\[
\mathcal{A}w = -\sum_{i=1}^n \frac{\partial}{\partial x_i} \left( \sum_{j=1}^n a_{ij}(x) \frac{\partial w}{\partial x_j} \right) \\
= -\text{div}_0(A(x) \nabla_0 w) = -\text{div}_0(\nabla_g w), \quad w \in C^2(\Omega).
\]
(2.15)

**Covariant Differential**

Denote the Levi–Civita connection in the Riemannian metric \( g \) by \( D \).
Let
\[
H = \sum_{k=1}^n h_k \frac{\partial}{\partial x_k}, \quad X = \sum_{k=1}^n \xi_k \frac{\partial}{\partial x_k},
\]
(2.16)
be vector fields on \( (\mathbb{R}^n, g) \). The covariant differential \( DH \) of \( H \) determines a bilinear form on \( \mathbb{R}^n \times \mathbb{R}^n \), for each \( x \in \mathbb{R}^n \), defined by
\[
DH(Y, X) = \langle DX H, Y \rangle_g, \quad \forall X, Y \in \mathbb{R}^n,
\]
(2.17)
where \( DX H \) is the covariant derivative of \( H \) with respect to \( X \). This is computed as follows, in the notation of (2.16), (2.11), by using the axioms of a connection,
\[
DX H = \sum_{k=1}^n DX \left( h_k \frac{\partial}{\partial x_k} \right) = \sum_{k=1}^n X(h_k) \frac{\partial}{\partial x_k} + \sum_{k=1}^n h_k DX \left( \frac{\partial}{\partial x_k} \right) \\
= \sum_{k=1}^n X(h_k) \frac{\partial}{\partial x_k} + \sum_{k, i=1}^n h_k \xi_i DX \left( \frac{\partial}{\partial x_k} \right),
\]
(2.18)
where by definition, see (2.11),

$$X(h_k) = \langle \nabla_g h_k, X \rangle_g = X \cdot \nabla_g h_k = \sum_{i=1}^{n} \xi_i \frac{\partial h_k}{\partial x_i}$$

(2.19)

$$D_{\partial/\partial x_i} \left( \frac{\partial}{\partial x_k} \right) = \sum_{l=1}^{n} \Gamma_{ikl} \frac{\partial}{\partial x_l}$$

\(\Gamma_{ikl}\) being the connection coefficients (Christoffel symbols) of the connection \(D\),

\(\Gamma_{ikl} = \frac{1}{2} \sum_{p=1}^{n} a_{lp} \left( \frac{\partial g_{kp}}{\partial x_i} + \frac{\partial g_{ip}}{\partial x_k} - \frac{\partial g_{ik}}{\partial x_p} \right)\), \((g_{ij}) = (a_{ij})^{-1}\). (2.20)

Inserting (2.20) into (2.19), and then (2.19) into (2.18), yields

$$D_X H = \sum_{k=1}^{n} X(h_k) \frac{\partial}{\partial x_k} + \sum_{l=1}^{n} \left( \sum_{k,i=1}^{n} h_k \xi_i \Gamma_{ikl} \right) \frac{\partial}{\partial x_l}$$

$$= \sum_{l=1}^{n} \left[ X(h_l) + \sum_{k,i=1}^{n} h_k \xi_i \Gamma_{ikl} \right] \frac{\partial}{\partial x_l}. \quad (2.21)$$

Finally, inserting (2.21) into (2.17), we obtain by (2.2), (2.16), and (2.19) for \(X(h_l)\):

$$DH(X, X) = \langle D_X H, X \rangle_g$$

$$= \sum_{l, i=1}^{n} \left[ X(h_l) + \sum_{k,i=1}^{n} h_k \xi_i \Gamma_{ikl} \right] \xi_i g_{lj}$$

(by (2.19))

$$= \sum_{i, j=1}^{n} \left[ \sum_{l=1}^{n} \frac{\partial h_l}{\partial x_l} g_{lj} + \sum_{k,l=1}^{n} h_k g_{lj} \Gamma_{ikl} \right] \xi_i \xi_j. \quad (2.23)$$

Thus, in \(\mathbb{R}^n \times \mathbb{R}^n\), \(DH(\cdot, \cdot)\) is equivalent to the \(n \times n\) matrix

$$\begin{pmatrix}
  m_{ij} = \sum_{l=1}^{n} \frac{\partial h_l}{\partial x_l} g_{lj} + \sum_{k,l=1}^{n} h_k g_{lj} \Gamma_{ikl}, & i, j = 1, \ldots, n.
\end{pmatrix} \quad (2.24)$$
Hessian in the Riemannian Metric $g$

Let $f \in C^2(\mathbb{R}^n)$. By definition, the Hessian of $f$ with respect to the metric $g$ is

$$D^2 f(X, X) = \langle D_X(\nabla_g f), X \rangle_g$$

(2.25)

$$= \sum_{i,j=1}^{n} \xi_i \left( \sum_{l=1}^{n} \frac{\partial f}{\partial x_l} g_{lj} + \sum_{k,l=1}^{n} f_k g_{lj} \Gamma_{ik}^l \right) \xi_j,$$

(2.26)

where, by (2.10), $f_i = (\nabla_g f)_i$ is the $i$th coordinate of $\nabla_g f$:

$$(\nabla_g f)_i = f_i = \sum_{p=1}^{n} a_{ip} \frac{\partial f}{\partial x_p}, \quad i = 1, 2, \ldots, n.$$  

(2.27)

To prove (2.26), we recall (2.21) with $H = \nabla_g f$, hence with coordinates $h_i = (\nabla_g f)_i = f_i$ as in (2.27), and obtain by (2.19):

$$D_X(\nabla_g f) = \sum_{i=1}^{n} \left[ \sum_{l=1}^{n} \xi_l \frac{\partial f}{\partial x_l} \delta_{il} + \sum_{k,l=1}^{n} f_k \xi_l \Gamma_{ik}^l \right] \frac{\partial}{\partial x_i}.$$  

(2.28)

Thus, (2.2), (2.16) for $X$, and (2.28) yield

$$\langle D_X(\nabla_g f), X \rangle_g = \sum_{l,q=1}^{n} g_{lq} \left[ \sum_{i=1}^{n} \xi_i \frac{\partial f}{\partial x_i} \delta_{il} + \sum_{k,l=1}^{n} f_k \xi_l \Gamma_{ik}^l \right] \xi_q$$

(2.29)

$$= \sum_{l,q,i=1}^{n} g_{lq} \xi_i \frac{\partial f}{\partial x_i} \xi_q + \sum_{l,q,k,i=1}^{n} g_{lq} f_k \xi_l \Gamma_{ik}^l \xi_q,$$

(2.30)

$$= \sum_{i,q=1}^{n} \xi_i \left( \sum_{l=1}^{n} g_{lq} \frac{\partial f}{\partial x_l} \right) \xi_q$$

$$+ \sum_{i,q=1}^{n} \xi_i \left( \sum_{l,k=1}^{n} g_{lq} f_k \Gamma_{ik}^l \right) \xi_q,$$

(2.31)

and (2.31) proves (2.26), as desired with $q = j$.

Thus, by (2.26), we have that

$$D^2 f$$ is positive on $\mathbb{R}^n \times \mathbb{R}^n$ if and only if the $n \times n$ matrix

$$m_{ij} = \sum_{l=1}^{n} \frac{\partial f}{\partial x_l} g_{lj} + \sum_{k,l=1}^{n} f_k g_{lj} \Gamma_{ik}^l,$$

(2.32)

$$i, j = 1, \ldots, n,$$ is positive, with $f_i$ given by (2.27).
Remark 2.1. Let the coefficients $a_{ij}$ in (1.1) be of class $C^1$, as assumed. Then, the entries $g_{ij}$ in (2.1) are of class $C^1$ as well. Thus, the connection coefficients $\Gamma^l_{ij}$ in (2.20) are of class $C^0$. The geodesics-solutions to a corresponding second order non-linear ordinary differential equation are then of class $C^2$. Thus, the square of the distance function $d^2(x, x_0)$, see Example 8.1 is in $C^2$. This is sufficient for the estimates below in the case of second order hyperbolic equations. In our case, where the manifolds are complete, the geodesics exist globally.

3. MAIN RESULTS. PRELIMINARIES

Let the domain $\Omega$ and the elliptic operator $\mathcal{A}$ in (1.1) be given satisfying the standing assumption (H.1) = (1.2). The additional hypothesis which we shall need to establish the continuous observability inequalities (1.5) and (1.8) is the following.

Main Assumption (H.3)

We assume that there exists a function $\varphi_0: \overline{\Omega} \to \mathbb{R}$ of class $C^2$ which is strictly convex on $\overline{\Omega}$ with respect to the Riemannian metric $g$ defined in Section 2. For purposes of (3.4) below, we translate $\varphi(x)$ as to make it nonnegative on $\overline{\Omega}$, and set

$$0 \leq \varphi(x) = \varphi_0(x) - \min_{x \in \Omega} \varphi_0(x).$$

This assumption means that the Hessian of $\varphi$ in the Riemannian metric $g$ is positive on $\overline{\Omega}$, as defined by (2.25), (2.32):

$$D^2 \varphi(X, X)(x) > 0, \quad \forall x \in \overline{\Omega}, \quad X \in \mathbb{R}^n.$$  

Since $\overline{\Omega}$ is compact, it follows from (3.2a) that there exists a positive constant $\rho > 0$ such that

$$D^2 \varphi(X, X) \geq 2 \rho |X|^2_g, \quad \forall x \in \overline{\Omega}, \quad X \in \mathbb{R}^n.$$  

Under assumption (H.3), we then take the vector field

$$h(x) = \nabla_g \varphi(x) = \sum_{i=1}^n \left( \sum_{j=1}^n a_{ij}(x) \frac{\partial \varphi}{\partial x_j} \right) \frac{\partial}{\partial x_i},$$

defined as the gradient of $\varphi(x)$ with respect to the Riemannian metric $g$, see (2.10).
When $F_1 = 0$ in [28] (or else when $F_1$ is zero order), the above assumption (3.26) can be weakened, within the present Riemann geometric approach, to read: there exists a vector field $H$ on the Riemann manifold $(\mathbb{R}^n, g)$ such that

$$\langle D_X H, X \rangle_g \geq a|X|^2_g \quad \forall X \in \mathbb{R}^n, \quad x \in \Omega$$

for some constant $a > 0$. In this assumption, the required vector field $X$ need not be the covariant differential of a function [28, Example 3.4], unlike (3.3) above.

Section 8 below will provide some nontrivial illustrations where the standing assumption H.1 as well as the main assumption H.3 are guaranteed to hold true, in the spirit of more general results as in [28, Section 1].

**Main Results. Continuous Observability Inequalities**

We are now in the position to state our main results concerning the validity of the continuous observability inequalities (1.5) and (1.8) for the Dirichlet and the Neumann case, respectively. First, define

$$T_0 = 2\left(\max_{x \in \Omega} v(x) / \rho\right)^{1/2} \quad \rho \text{ as in (3.2b).}$$

**Remark 3.1.** Both Theorems 3.1 and 3.2 below require a uniqueness continuation result for the hyperbolic $\psi$-problem (1.4), respectively (1.7), with over-determined B.C.,

$$\frac{\partial \psi}{\partial n'} \bigg|_{\Sigma_t} = 0 \quad \text{for Theorem 3.1;} \quad \psi|_{\Sigma} = 0 \quad \text{for Theorem 3.2,} \quad (3.5)$$

which asserts that, then, $\psi = 0$ in $Q$, for $T$ as given. This uniqueness continuation result is needed to absorb the lower-order term from estimates (5.2.13), respectively (7.1), through a (by now standard) compactness/uniqueness argument. Global uniqueness continuation results, precisely as stated above—i.e., precisely as needed below in Theorem 3.1 (Dirichlet case) and in Theorem 3.2 (Neumann case)—have been obtained very recently see [30] in the Dirichlet case and particularly [18b] in both the Dirichlet and the Neumann case, at least when $\mathcal{A} = -\Delta$, under some geometrical conditions. Here, moreover, $T$ is the ‘optimal time’ related to the finite speed of propagation. In addition, known uniqueness continuation results mostly though of local character, include the following cases:

(a) The case where the coefficients $a_{ij}$ of the principal part are time-independent and of class $C^V(\Omega)$, as assumed; while the coefficients of
the first-order operator $F$ in (1.4a), or (1.7a), are analytic in time and in $L_\omega(Q)$, as assumed in (1.3). In this case, a local uniqueness continuation result, of the type noted above, [26, Section 5.1, p. 882], see also [7].

The subcase, where the coefficients of $F$ are also time-independent and in $L_\omega(Q)$, appears also in [9, Corollary 3.4.3, p. 63], still in a local version. Here, another approach is as follows. The aforementioned uniqueness continuation results for the hyperbolic over-determined problem can, in turn, be reduced [1] to a corresponding second-order over-determined elliptic problem to which we apply a corresponding elliptic uniqueness result. [6, Theorem 17.2.6, p. 14].

(b) The case of (real) analytic data covered by Holmgren-John's theorem [9, p. 52, 6] (semi-global, optimal version).

(c) The case where $-\mathcal{A} = \Delta / a_0$, with $a_0 \in C^1(\Omega)$, time-independent, $a_0 > 0$, but the coefficients of $F$ possibly time-dependent in $L_\omega(Q)$, which is covered by [9, Theorem 3.4.1], in a local version, with a global version when $\Gamma_1 = \Gamma$.

**Theorem 3.1 (Dirichlet case).** Let $\Omega$, $\mathcal{A}$, and $F$ satisfy the standing assumptions (H.1) = (1.2), (H.2) = (1.3). Let assumption (H.3) = (3.2) hold true and define $h(x)$ by (3.3). Let $T > T_0$, see (3.4). Assume that $h(x) \cdot \nu(x) \leq 0$ for $x \in \Gamma_0$, where we recall that $\nu(x) = [\nu_1(x), \ldots, \nu_n(x)]$ is the unit outward normal vector to $\Gamma$, and where $h(x) \cdot \nu(x) = \Sigma_{i=1}^n h_i(x) \nu_i(x)$ is the dot product in $\mathbb{R}^n$. Assume the uniqueness continuation property of the over-determined problem (1.4) with $(\partial \psi / \partial \nu)_{\Gamma_0} = 0$, as described in Remark 3.1 above. Then, the observability inequality (1.5) for the Dirichlet $\psi$-problem (1.4) holds true.

In the next result, unlike much of the literature [19], [28], and in line with [15], [17], we impose no geometrical conditions on the controlled/observed part of the boundary $\Gamma_1$.

**Theorem 3.2 (Neumann case).** Let $\Omega$, $\mathcal{A}$, and $F$ satisfy the standing assumptions (H.1), (H.2). Let assumption (H.3) hold true and define $h(x)$ by (3.3). Let $\Gamma_0$ and $\Gamma_1$ be given, $\Gamma = \Gamma_0 \cup \Gamma_1$, $\Gamma_0 \neq \emptyset$, $\Gamma_0 \cap \Gamma_1 = \emptyset$, and $h(x) \cdot \nu(x) \leq 0$ for $x \in \Gamma_0$. Let $T > T_0$, see (3.4). Assume the uniqueness continuation property of the over-determined problem (1.7) with $\psi|_{\Gamma_1} = 0$, as described in Remark 3.1. Then, the observability inequality (1.8) for the Neumann $\psi$-problem (1.7) holds true.

Remark 3.2. $T_0$, defined in (3.4), is sharp even in the case of constant coefficients with a radial vector field. If $\nu(x)$ is the square of the distance function, then $\rho = 1$ and $T_0$ is equal to the diameter of $\Omega$. We also note that the square of the distance function $d^2(x, x_0)$ in the Riemann metric is always locally strictly convex, so that, if $\Omega$ is “sufficiently small”, the above results are applicable.
Carleman Estimates

The results of Theorems 3.1 and 3.2 can be shown as a consequence of suitable Carleman estimates for (1.4a) with no boundary conditions imposed, which we now describe.

Let $v : \overline{\Omega} \to \mathbb{R}$ be the strictly convex function, with respect to the Riemannian metric $g$, provided by assumption (H.3). Define the function $\phi : \Omega \times \mathbb{R} \to \mathbb{R}$ by

$$\phi(x, t) = v(x) - c \left| t - \frac{T}{2} \right|^2, \quad (3.6a)$$

where $T > T_0$, see (3.4), and $c$ is a constant chosen below as follows. Let $T > T_0$ be given. By (3.4), there is $\delta > 0$ such that

$$\rho T^2 > 4 \max_{x \in \Omega} v(x) + 4\delta.$$

For this $\delta$, there is then a constant $c , 0 < c < \rho$, such that

$$cT^2 > 4 \max_{x \in \Omega} v(x) + 4\delta , \quad 0 < c < \rho. \quad (3.6b)$$

Henceforth, let $\phi$ be defined by (3.6a) with the above $c$ as in (3.6b) unless otherwise explicitly noted. Such function $\phi(x, t)$ has then the following properties:

(i) $\phi(x, 0) < -\delta$ and $\phi(x, T) < -\delta$ uniformly in $x \in \Omega$; \hspace{1cm} (3.6c)

(ii) there are $t_0$ and $t_1$ with $0 < t_0 < T/2 < t_1 < T$ such that

$$\min_{x \in \Omega, t \in [t_0, t_1]} \phi(x, t) \geq -\frac{\delta}{2}, \quad (3.6d)$$

since $\phi(x, T/2) = v(x) \geq 0$ for all $x \in \Omega$;

(iii) recalling (3.3),

$$\nabla_g \phi = \nabla_g v = h; \quad \phi_t(x, t) = -2c \left( t - \frac{T}{2} \right), \quad (3.6e)$$

and $\phi_{tt} = -2c; \quad \phi_t(x, 0) = cT; \quad \phi(x, T) = -cT.$

The important property (3.6c) will be invoked in the proof of (4.2.26) of Lemma 4.2.5 leading to Theorem 3.3, (3.9a). The important property (3.6d) (in fact, only the weaker property: $\min \phi(x, t) \geq \sigma > -\delta$ is actually
The following result is a counterpart of [17, Theorem 2.1.1].

**Theorem 3.3** (Carleman estimates, first version). Assume (H.1), (H.2), and (H.3). Let \( f \in L^2(Q) \). Let \( w \) be a solution of the second-order hyperbolic equation

\[
  w_{tt} + \omega w = F_t(w) + f \quad \text{in } Q
\]

(with no boundary conditions imposed), within the following class:

\[
  w \in H^{1,1}(Q) = L^2(0,T; H^1(\Omega)) \cap H^1(0,T; L^2(\Omega))
\]

\[
  w_t, \quad \frac{\partial w}{\partial \nu} \in L^2(0,T; L^2(\Gamma)).
\]

Let \( \phi(x,t) \) be the function defined by (3.6a), and \( C_T \) a generic constant.

Then, for \( \tau > 0 \), the following one-parameter family of estimates holds true,

\[
  (BT_w)_\Sigma + \frac{C_T}{\tau} \int_Q e^{\omega \phi} f^2 \, dQ + TC_T \text{const}_\tau \|w\|^2_{C([0,T]; L^2(\Omega))} \geq \left( \rho - c - \frac{C_T}{\tau} \right) \int_Q e^{\omega \phi} \left[ |\nabla w|^2 + w_t^2 \right] \, dQ
\]

\[
  - C(1 + \tau) e^{-\delta \tau} [E(T) + E(0)]
\]

\[
  \geq \left( \rho - c - \frac{C_T}{\tau} \right) e^{-(\delta / 2)}
\]

\[
  \times \int_{t_0}^t E(t) \, dt - C(1 + \tau) e^{-\delta \tau} [E(T) + E(0)],
\]

where the boundary terms \((BT_w)_\Sigma\) over \( \Sigma = [0,T] \times \Gamma \) are given by

\[
  (BT_w)_\Sigma = \int_{\Sigma} e^{\omega \phi} \frac{\partial w}{\partial \nu} [h(w) - \phi w_t] \, d\Sigma
\]

\[
  + \int_{\Sigma} \frac{\partial w}{\partial \nu} w \left[ \frac{1}{2} \mu - (1 + c) e^{\omega \phi} \right] d\Sigma
\]

\[
  + \frac{1}{2} \int_{\Sigma} e^{\omega \phi} \left[ w_t^2 - |\nabla w|^2 \right] h \cdot \nu \, d\Sigma,
\]

with \( \mu(x,t) \) a suitable function depending on \( \phi \), defined in (4.2.14) below. Moreover, we have set for convenience

\[
  E(t) = E_w(t) = \int_{\Omega} \left[ |\nabla w(t,x)|^2 + w_t^2(t,x) \right] \, d\Omega,
\]
and we recall that $h(w) = \langle h, \nabla_x w \rangle_s = \langle \nabla_x \nu, \nabla_x w \rangle_s = \nabla_x w \cdot h$ by (2.8) and (2.11), with $h$ the vector field defined by (3.3).

**Remark 3.3.** By (2.13), (1.2a), we have

$$a |\nabla_0 w(t, x)|^2 \leq |\nabla_s w(t, x)|^2 = \nabla_0 w(t, x) \cdot A(x) \nabla_0 w(t, x)$$

$$\leq a_1 |\nabla_0 w(t, x)|^2, \quad x \in \Omega,$$

where $a > 0$ is the constant in (1.2a). Thus, by (3.11) and (3.12), we have that

$$E(t)$$ is equivalent to $\|w(t), w(t)\|_{H^1(\Omega) \times L^2(\Omega)}^2$ if $w|\Sigma_0 = 0, \quad \Gamma_0 \neq \emptyset.$

(3.13)

We shall henceforth use (3.13) freely, particularly for $t = 0$ and $t = T$.

**Remark 3.4.** Property (3.6c) is used to obtain (3.9a). Property (3.6d) is used to obtain (3.9b).

The proof of Theorem 3.3 is given in Section 4. The counterpart of [17, Theorem 2.1.2] is the following.

**Theorem 3.4 (Carleman estimates, second version).** Assume the hypotheses of Theorem 3.3. Then, for all $\tau > 0$ sufficiently large, there exists a constant $k_{\phi, \tau} > 0$ such that the following one-parameter family of estimates holds true,

$$(BT_w)|_\Sigma + \frac{C_T}{\tau} \int_Q e^{cT} f^2 dQ + C_T \text{const.} \|w\|_{L^2(0, T; L^2(\Omega))}^2$$

$$\geq e^{-((\tau/2))} \left( \rho - c - \frac{C_T}{\tau} \right) e^{-C_T(1 + \tau)} e^{-((\tau/2))}$$

$$\times [E(T) + E(0)] - C(1 + \tau) e^{-((\tau/2))}$$

$$\geq k_{\phi, \tau} [E(T) + E(0)],$$

(3.14)

$C_T$ a generic constant, where the boundary terms $(BT_w)|_\Sigma$ over $\Sigma = (0, T) \times \Gamma$ are given by

$$(BT_w)|_\Sigma = (BT_w)|_\Sigma + \text{const.} \phi, \tau \int_\Sigma \frac{\partial w}{\partial \nu} w \nu d\Sigma,$$

(3.15)

with $(BT_w)|_\Sigma$ defined by (3.10).

Assume, further, that the solution $w$ of (3.7) satisfies

$$w|\Sigma_0 = 0, \quad \Sigma_0 = (0, T) \times \Gamma_0, \quad \text{and} \quad h(x) \cdot \nu(x) \leq 0, \quad x \in \Gamma_0,$$

(3.16)
with $h = \nabla_g \phi = \nabla_g \psi$ by (3.6e), and $\nu(x)$ the unit outward normal vector at $x \in \Gamma$.

Then, estimate (3.15) holds true for $\tau > 0$ sufficiently large, with the boundary terms $(\mathcal{B}_w)|\Sigma$ replaced by $(\mathcal{B}_w)|\Sigma_1$, i.e., evaluated only on $\Sigma_1 = (0, T] \times \Gamma_1$, while the boundary terms $(\mathcal{B}_w)|\Sigma_0$ evaluated on $\Sigma_0 = (0, T] \times \Gamma_0$ are negative: $(\mathcal{B}_w)|\Sigma_0 \leq 0$ (see (6.2) below for the precise expression of $(\mathcal{B}_w)|\Sigma_0$).

The proof of Theorem 3.4 is given in Section 5.1. Estimate (3.15) of Theorem 3.4 then readily yields Theorem 3.1 on the continuous observability inequality (1.5) in the Dirichlet case for $\psi = w$ with $f = 0$, $\psi|\Sigma = 0$, and $h \cdot \nu \leq 0$ on $\Gamma_0$. This is done in Section 5.2. However, to prove Theorem 3.2 on the continuous observability inequality in the Neumann case for $\psi = w$ with $f = 0$, $\psi|\Sigma_0 = 0$, $\Gamma_0 \neq \emptyset$, and $h \cdot \nu \leq 0$ on $\Gamma_0$, an additional nontrivial step is needed. This is provided by a key result of [15] which will be quoted in Lemma 6.2 below. Combined with Theorem 3.4, this result will permit us to obtain the following theorem, which may be viewed as the main estimate at the energy level of the present paper, the counterpart of [17, Theorem 2.1.5].

**Theorem 3.5.** Assume (H.1), (H.2), (H.3), and that $f \in L^2(Q)$. Let $w$ be a solution of (3.7) in the class (3.8).

(a) Then, the following estimate holds true. There exists a constant $k_{\phi, \tau} > 0$ for $\tau$ sufficiently large such that, for any $\epsilon_0 > 0$,

$$
\int_0^T \int_{\Gamma_1} \left[ \frac{\partial w}{\partial \nu_{\phi, \tau}} \right]^2 + w^2 \, d\Sigma + \text{const}_{\phi, \tau} \int_Q f^2 \, dQ + C_{\phi, \epsilon_0} \|w\|^2_{L^2(0, T; H^{1/2 - \epsilon_1}(\Gamma_1))} \\
\geq k_{\phi, \tau} \left[ E(T) + E(0) \right].
$$

(b) Assume, further, that the solution $w$ of (3.7) satisfies hypothesis (3.17).

Then, estimate (3.18) holds true with $\int_\Gamma$ replaced by $\int_{\Gamma_0}$.

Not only does estimate (3.18) imply the continuous observability inequality (1.8) for $\psi = w$, under the required assumption (3.17),

$$
\psi|\Sigma_0 = 0, \quad \Gamma_0 \neq \emptyset, \quad h \cdot \nu \leq 0 \text{ on } \Gamma_0; \quad \text{and} \quad \frac{\partial \psi}{\partial \nu_{\phi, \tau}} |_{\Sigma_1} = 0,
$$

by dropping $E(T)$ in (3.18) and by absorbing the lower-order interior term by compactness/uniqueness. Moreover, (3.18) implies also an inverse, or recovery, estimate for the following closed loop problem with explicit
dissipative feedback in the Neumann B.C.:
\begin{align}
  w_t + \alpha w &= F_1(w), \quad (3.19a) \\
  w(0, \cdot) &= w_0, \quad w_t(0, \cdot) = w_1, \quad (3.19b) \\
  w|_{\Sigma_0} &= 0, \quad (3.19c) \\
  \frac{\partial w}{\partial v_\omega} \bigg|_{\Sigma_1} &= -w_t. \quad (3.19d)
\end{align}

Part (i) of the following result is standard (perturbation of the dissipative case $F_1 = 0$, handled by Lumer–Phillips theorem); part (ii)—a recovery, or inverse, estimate—follows from Theorem 3.15 via compactness/uniqueness; see Remark 3.1.

**Theorem 3.6.** With reference to the closed loop problem (3.19), we have:

(i) when $\Gamma_0 \not= \emptyset$, under assumptions (H.1) and (H.2) for $\mathcal{A}$ and $F_1$, problem (3.19) generates a s.c. semigroup $\{w_0, w_1\} \in Y \rightarrow \{w(t), w_t(t)\} \in C([0, T]; Y)$, $Y = H^1_0(\Omega) \times L_2(\Omega)$;

(ii) when $\Gamma_0 = \emptyset$, the same result, under (H.1), (H.2), holds true, with $Y = H^1(\Omega) \times L_2(\Omega)$ replaced now by its proper subspace

\[ Y_0 = \left\{ [u_1, u_2] \in Y : \int_{\Gamma_1} u_1 \, d\Gamma + \int_{\Omega} u_2 \, d\Omega = 0 \right\}, \quad (3.20) \]

topologized by (see (4.1.1) below)

\[ \| [u_1, u_2] \|_{Y_0}^2 = \int_{\Omega} \left[ |\nabla u_1|^2 + u_2^2 \right] \, d\Omega, \quad (3.21) \]

which is a norm on $Y_0$ (but only a seminorm on $Y$). The operator \( \begin{bmatrix} 0 & 1 \\ -\alpha & 0 \end{bmatrix} \), with domain

\[ \mathcal{D} = \left\{ [u_1, u_2] \in H^2(\Omega) \times H^1(\Omega) : \frac{\partial u_1}{\partial v_\omega} = -u_2 \right\}, \quad (3.22) \]

is dissipative on $Y_0$, since, by (4.1.1) below,

\[ \begin{bmatrix} 0 & I \\ -\alpha & 0 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = -\int_{\Gamma_1} u_2^2 \, d\Gamma; \quad (3.23) \]

moreover, it is maximal dissipative on $Y_0$, since

\[ \begin{bmatrix} \lambda I - \begin{bmatrix} 0 & I \\ -\alpha & 0 \end{bmatrix} \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} f_1 \\ f_2 \end{bmatrix}, \quad [u_1, u_2] \in \mathcal{D} \quad (3.24) \]
means, via (4.1.1) below,
\[
\lambda \left[ \int_{\Gamma} u_1 \, d\Gamma + \int_{\Omega} u_2 \, d\Omega \right] = \int_{\Gamma} f_1 \, d\Gamma + \int_{\Omega} f_2 \, d\Omega, \quad (3.25)
\]
so that, given \([f_1, f_2] \in Y_0, \) (3.24) has a unique solution \([u_2, u_2] \in \mathcal{D}\) for \(\lambda > 0\), which, moreover, satisfies the side condition of \(Y_0\) in (3.20), by virtue of (3.25);

(iii) under the additional assumption \((H.3)\), and the uniqueness continuation property of Remark 3.1, the following inequality holds: for all \(T\) sufficiently large, there exists a positive constant \(k_{\phi, \tau} > 0\) such that
\[
\int_0^T \int_{\Gamma_1} \left( \frac{\partial w}{\partial \nu_{\phi}} \right)^2 \, d\Sigma_1 \geq \left\{ \begin{array}{l}
\kappa_{\phi, \tau} E(T); \\
\kappa_{\phi, \tau} E(0).
\end{array} \right. \quad (3.26)
\]

Remark 3.5. When \(F_1 = 0\) in (3.19a), estimate (3.26) implies (is equivalent to) uniform stabilization of problem (3.19): there exist constants \(M \geq 1, \, a > 0\) such that \(E(t) \leq Me^{-at}E(0)\), where \(\sqrt{E(\cdot)}\) is the \(Y = H_{\phi, \tau}^{1}(\Omega) \times L_2(\Omega)\)-norm (case (i)), or the \(Y_2\)-norm in (3.21) (case (ii)), where Remark 3.3 is relevant of the solution \((w, w, )\) of (3.19).

4. PROOF OF THEOREM 3.3: CARLEMAN ESTIMATE
(FIRST VERSION)

4.1. Preliminaries

We collect here a few formulas to be invoked in the sequel.

**A Green’s formula.** Below, in the proof of Proposition 4.2.1, (4.2.7) as well as of Lemma 4.2.2, (4.12), we shall make use of the following Green’s formula. Let \(z(x) \in C^4(\Omega)\). Then, the following identity holds true:
\[
\int_{\Omega} (\mathcal{A} w) z \, d\Omega = \int_{\Omega} \langle \nabla_{\mathcal{A}} w, \nabla z \rangle \, d\Omega - \int_{\Gamma} z \frac{\partial w}{\partial \nu_{\mathcal{A}}} \, d\Gamma. \quad (4.1.1)
\]
In fact, to prove (4.1.1), we write, by recalling (2.15) for \(\mathcal{A} w\), and the usual divergence formula [14, (A.1)],
\[
\int_{\Omega} (\mathcal{A} w) z \, d\Omega = -\int_{\Omega} z \, \text{div}_0(\nabla_{\mathcal{A}} w) \, d\Omega \quad (4.1.2)
\]
\[
= \int_{\Omega} \nabla_{\mathcal{A}} w \cdot \nabla_0 z \, d\Omega - \int_{\Gamma} z \nabla_{\mathcal{A}} w \cdot \nu \, d\Gamma. \quad (4.1.3)
\]
Then, recalling identity (2.11), and (2.12) for \(\partial w/\partial \nu_{\phi}\), we see that (4.1.3) leads to (4.1.1), as desired.
An identity. Let $\phi$ be the function in (3.6a). Let $H = e^{r \phi} h$, with $h = \nabla_g \phi$ by (3.6e). Finally, let $X = \nabla_g w$. Then, the following identity to be invoked in the proof of Proposition 4.2.1, Eqn. (4.2.9), holds true,

$$DH(X, X) = \langle D_X H, X \rangle_g = \langle D_{\nabla_g w}(e^{r \phi} h), \nabla_g w \rangle_g \tag{4.1.4}$$

$$= \tau e^{r \phi} [h(w)]^2 + e^{r \phi} D^2 h(\nabla_g w, \nabla_g w) \tag{4.1.5}$$

where we have recalled (2.22), and where $h(w) = \langle \nabla_g w, h \rangle_g$ by (2.11).

Proof of (4.1.5). We preliminarily compute, by using the axioms of the connection $D$,

$$D_X H = D_X (e^{r \phi} h) = X \cdot \nabla_0 (e^{r \phi}) h + e^{r \phi} D_X h
= \tau e^{r \phi} X \cdot \nabla_0 \phi h + e^{r \phi} D_X h. \tag{4.1.6}$$

Thus, (4.1.6) yields by (2.11),

$$\langle D_X H, X \rangle_g = \tau e^{r \phi} X(\phi) \langle h, X \rangle_g + e^{r \phi} \langle D_X h, X \rangle. \tag{4.1.7}$$

As to the second term in (4.1.7), with $h = \nabla_g \phi$ by (3.6e), we have, recalling definition (2.25) of Hessian of $\phi$:

$$\langle D_X h, X \rangle_g = \langle D_X (\nabla_g \phi), X \rangle_g = D^2 h(X, X). \tag{4.1.8}$$

As to the first term in (4.1.7), we have with $X = \nabla_g w, h = \nabla_g \phi$, recalling (2.8) or (2.11):

$$X(\phi) = \langle \nabla_g \phi, X \rangle_g = \langle h, X \rangle_g = \langle h, \nabla_g w \rangle_g = h(w). \tag{4.1.9}$$

Thus, (4.1.8) and (4.1.9), used on the R.H.S. of (4.1.7) yields for $X = \nabla_g w, h = \nabla_g \phi$:

$$\langle D_X h, X \rangle_g = \tau e^{r \phi} [h(w)]^2 + e^{r \phi} D^2 h(X, X), \tag{4.1.10}$$

which, in turn, proves (4.1.5).

A second identity. Let $\phi$ be the function in (3.6a). The following identity, to be invoked in the proof of Proposition 4.2.1, Eqn. (4.2.11), holds true

$$\langle \nabla_g w, \nabla_g [e^{r \phi} \phi w] \rangle_g = \tau e^{r \phi} \phi w h(w) + \frac{1}{2} e^{r \phi} \frac{d}{dt} |\nabla_g w|^2. \tag{4.1.11}$$
Proof of (4.1.11). Since $\phi$, does not depend on $x$, by (3.6e), invoking identity (2.13), we obtain
\[
\langle \nabla_g w, \nabla_g [e^{r\phi} \phi w_i] \rangle_g = \nabla_0 [e^{r\phi} \phi w_i] \cdot \nabla_g w
= r e^{r\phi} \omega, \nabla_0 \phi \cdot \nabla_g w + e^{r\phi} \nabla_0 w_i \cdot \nabla_g w, \tag{4.1.12}
\]
where, with $h = \nabla_g \phi$ by (3.6e), and recalling (2.11), we have
\[
\nabla_0 \phi \cdot \nabla_g w = \langle \nabla_g \phi, \nabla_g w \rangle_g = \langle h, \nabla_g w \rangle_g = h(w); \tag{4.1.13}
\]
\[
\nabla_0 w_i \cdot \nabla_g w = \langle \nabla_g w_i, \nabla_g w \rangle_g = \frac{1}{2} \frac{d}{dt} |\nabla_g w|^2. \tag{4.1.14}
\]
Inserting (4.1.13) and (4.1.14) in (4.1.12) yields (4.1.11), as desired.

4.2. Energy Methods in the Riemann Metric

We will complete the proof of Theorem 3.3 through several propositions. The strategy follows closely the proof of [17, Section 2] for constant coefficient principal part $\mathcal{A} = -\Delta$, except that it is carried out in the Riemann metric $g$ defined by (2.2), rather than in the Euclidean metric as in [17]. The close parallelism between the present treatment and that of [17] will be emphasized in the intermediate results as well. The counterpart of [17, Proposition 2.2.1] is

Step 1. Proposition 4.2.1. Let $w$ be a solution of (3.7) within the class $\Sigma = [0, T] \times \Gamma; Q = [0, T] \times \Omega.$

\[
\int_\Sigma e^{r\phi} \frac{\partial w}{\partial \nu} [h(w) - \phi w_i] d\Sigma + \frac{1}{2} \int_\Sigma e^{r\phi} [w_i^2 - |\nabla_g w|^2] h \cdot \nu d\Sigma
= \int_Q e^{r\phi} D^2 \phi (\nabla_g w, \nabla_g w) dQ + \frac{1}{2} \int_Q [w_i^2 - |\nabla_g w|^2] \text{div}_0 (e^{r\phi} h) dQ
+ \frac{1}{2} \int_Q \frac{d}{dt} (e^{r\phi} \phi_i) dQ + \tau \int_Q e^{r\phi} [h(w)]^2 dQ
- 2\tau \int_Q e^{r\phi} h(w) \phi_i w_i dQ + \left[ \int_\Omega e^{r\phi} [h(w) - \frac{1}{2} \phi w_i] w_i d\Omega \right]^T
- \frac{1}{2} \int_\Omega e^{r\phi} w_i^2 d\Omega \right]^T
- \int_Q [F_i(w) + f] e^{r\phi} [h(w) - w_i \phi_i] dQ. \tag{4.2.1}
\]
In (4.2.1), we have $h(x) = \nabla_x \phi = \nabla_x v(x)$, see (3.3), (3.6e), while $D^2\phi(\cdot \cdot \cdot)$ is the Hessian (as defined in (2.25)) of the function $\phi$ in (3.6a); finally, $h(w) = \langle h, \nabla_w \rangle_e = \langle \nabla_x v, \nabla_w \rangle_e = \nabla_v w \cdot h$ by (2.8), and (2.11), with the vector field $h$ defined by (3.3).

**Proof.** We multiply both sides of (3.7) by the main multiplier
\[ e^{\tau\phi(x,t)} \left[ h(w) - \phi w_t \right], \tag{4.2.2} \]
for counterpart of the one in [17, eqn. (2.2.1a)] and integrate over $Q = [0,T] \times \Omega$ by parts.

**Left-hand side.** We shall show below that on the left-hand side (L.H.S.) of (3.7) we obtain, recalling Lemma 2.1(b)–(e),
\[
\text{L.H.S.} = \int_0^T \int_\Omega w_t e^{\tau\phi} \left[ \nabla_x \phi(w) - \phi w_t \right] d\Omega \, dt \\
= \frac{1}{2} \int_Q w_t^2 \left[ \text{div}_0(e^{\tau\phi} h) + \frac{d}{dt}(e^{\tau\phi} \phi_t) \right] dQ \\
- \tau \int_Q e^{\tau\phi} h(w) \phi_t w_t \, dQ \\
- \frac{1}{2} \int_\Sigma e^{\tau\phi} w_t^2 h \cdot \nu \, d\Sigma + \left[ \int_\Omega e^{\tau\phi} \left[ h(w) - \frac{1}{2} \phi w_t \right] w_t \, d\Omega \right]_0^T, \tag{4.2.3}
\]
where $\nabla_x \phi = h$ by (3.6e), so that $\nabla_x \phi(w) = h(w) = \langle \nabla_x w, h \rangle_e = \nabla_v w \cdot h$ by (2.8), (2.11). Indeed, integrating by parts in $t$, and recalling that $\nabla_x \phi = h(x)$ is time-independent, we compute
\[
\int_\Omega \int_0^T \text{w_t} e^{\tau\phi} h(w) \, d\Omega \, dt = \left[ \int_\Omega e^{\tau\phi} w_t h(w) \, d\Omega \right]_0^T \\
- \tau \int_Q e^{\tau\phi} \phi_t w_t h(w) \, dQ + \int_Q e^{\tau\phi} w_t h(w) \, dQ. \tag{4.2.4}
\]
Now the last term in (4.2.4), where \( h(w_i) = h \cdot \nabla w_i \) by (2.11), is rewritten, by the usual formula for divergence [14, (A.1)], as

\[
\int_Q e^{\tau \phi} h(w_i) \, dQ = \frac{1}{2} \int_Q e^{\tau \phi} h(w_i^2) \, dQ = \frac{1}{2} \int_Q e^{\tau \phi} h \cdot \nabla w_i^2 \, dQ
\]

\[
= \frac{1}{2} \int_\Sigma e^{\tau \phi} w_i^2 \, d\Sigma - \frac{1}{2} \int_Q w_i^2 \, \text{div}_0 (e^{\tau \phi} h) \, dQ. \tag{4.2.5}
\]

Similarly, integrating by parts in \( t \), we compute

\[
\int_{\Omega}^{T} \int_{\Omega}^{T} e^{\tau \phi} w_i \, dt \, d\Omega = \frac{1}{2} \int_{\Omega}^{T} \int_{\Omega}^{T} e^{\tau \phi} \frac{d}{dt} (w_i^2) \, dt \, d\Omega
\]

\[
= \left[ \frac{1}{2} \int_{\Omega}^{T} e^{\tau \phi} w_i^2 \, d\Omega \right] - \frac{1}{2} \int_{\Omega}^{T} w_i d\Omega = \frac{1}{2} \int_{\Omega}^{T} e^{\tau \phi} d\Omega. \tag{4.2.6}
\]

Using (4.2.5) in (4.2.4) and subtracting off (4.2.6) yields (4.2.3), as desired.

**Right-hand side.** Multiplying the right-hand side (R.H.S.) \([-\phi' + F_i(w) + f]\) of (3.7) by the multiplier in (4.2.2), \( e^{\tau \phi}[h(w) - \phi w_i] \), and integrating over \( Q = [0, T] \times \Omega \), we obtain

\[
\text{R.H.S.} = - \int_{\Omega}^{T} \int_{\Omega}^{T} \left[ \phi' + \frac{d}{dt} (e^{\tau \phi} h) \right] \, dt
\]

\[
= \int_{\Omega}^{T} \int_{\Omega}^{T} e^{\tau \phi} \left[ h - \phi w_i \right] \frac{\partial w}{\partial \nu} \, d\Sigma - \frac{1}{2} \int_{\Omega}^{T} \left| \nabla w \right|^2 \, e^{\tau \phi} h \, d\Sigma
\]

\[
+ \frac{1}{2} \int_{\Omega}^{T} \left| \nabla w \right|^2 \left[ \text{div}_0 (e^{\tau \phi} h) - \frac{d}{dt} (e^{\tau \phi} \phi) \right] \, dQ
\]

\[
- \int_{\Omega}^{T} e^{\tau \phi} D^2 \phi (\nabla w, \nabla w) \, dQ - \tau \int_{\Omega}^{T} \left[ h(w) \right]^2 \, dQ
\]

\[
+ \tau \int_{\Omega}^{T} e^{\tau \phi} \phi_w h(w) \, dQ + \frac{1}{2} \left[ \int_{\Omega}^{T} e^{\tau \phi} \phi_w \nabla w^2 \, d\Omega \right] - \int_{\Omega}^{T} [F_i(w) + f] \, e^{\tau \phi} [h(w) - \phi w_i] \, dQ. \tag{4.2.7}
\]

where \( D^2(\ , \ ) \) is the Hessian (see (2.25)) of the function \( \phi \) defined by (3.6a).
Proof of (4.2.7). Indeed, using Green’s formula (4.1.1) with \( z = e^{\gamma_0}[h(w) - \phi_I w_I] \), we compute

\[
- \int_\Omega (\mathcal{A} w) e^{\gamma_0} [h(w) - \phi_I w_I] \, d\Gamma = \int_\Gamma e^{\gamma_0} [h(w) - \phi_I w_I] \frac{\partial w}{\partial n} \, d\Gamma
\]

\[
- \int_\Omega \langle \nabla_g w, \nabla_g [e^{\gamma_0} h(w)] \rangle_g \, d\Omega + \int_\Omega \langle \nabla_g w, \nabla_g [e^{\gamma_0} \phi_I w_I] \rangle_g \, d\Omega.
\]

(4.2.8)

As to the first integral over \( \Omega \) on the right-hand side of (4.2.8), we obtain from Lemma 2.1(f), (2.14), with \( H = e^{\gamma_0} h \), as well as by identity (4.1.5),

\[
\langle \nabla_g w, \nabla_g [e^{\gamma_0} h(w)] \rangle_g = D(e^{\gamma_0} h)(\nabla_g w, \nabla_g w) + \frac{1}{2} \text{div}_0(\|\nabla_g w\|^2 e^{\gamma_0} h)
\]

\[
- \frac{1}{2} \|\nabla_g w\|^2 \text{div}_0(e^{\gamma_0} h)
\]

(by (4.15))

\[
\tau e^{\gamma_0} [h(w)]^2 + e^{\gamma_0} D^2 \phi(\nabla_g w, \nabla_g w)
\]

\[
+ \frac{1}{2} \text{div}_0(\|\nabla_g w\|^2 e^{\gamma_0} h) - \frac{1}{2} \|\nabla_g w\|^2 \text{div}_0(e^{\gamma_0} h).
\]

(4.2.9)

We next integrate (4.2.9) over \( Q \), apply the divergence theorem

\[
\int_0^\tau \int_\Omega \langle \nabla_g w, \nabla_g [e^{\gamma_0} h(w)] \rangle_g \, d\Omega \, dt
\]

\[
= \frac{1}{2} \int_\Sigma e^{\gamma_0} \|\nabla_g w\|^2 h \cdot \nu \, d\Sigma + \tau \int_\Omega e^{\gamma_0} [h(w)]^2 \, dQ
\]

\[
+ \int_Q e^{\gamma_0} D^2 \phi(\nabla_g w, \nabla_g w) \, dQ - \frac{1}{2} \int_Q \|\nabla_g w\|^2 \text{div}_0(e^{\gamma_0} h) \, dQ.
\]

(4.2.10)
As to the second integral term over \( \Omega \) on the right-hand side of (4.2.8), we invoke identity (4.1.11) and integrate by parts,

\[
\int_0^T \int_{\Omega} \langle \nabla_g w, \nabla_g \left[ e^{r \phi_i} w_i \right] \rangle_g \, dQ = \tau \int_{\Omega} \int_0^T e^{r \phi_i} \frac{d}{dt} |\nabla_g w|^2 \, dt \, d\Omega
\]

(by (4.1.11))

\[
= \tau \int_{\Omega} \int_0^T e^{r \phi_i} w_i h(w) \, dQ + \frac{1}{2} \int_{\Omega} \int_0^T e^{r \phi_i} \frac{d}{dt} |\nabla_g w|^2 \, dt \, d\Omega
\]

\[
= \tau \int_{\Omega} e^{r \phi_i} w_i h(w) \, dQ + \frac{1}{2} \left[ \int_{\Omega} e^{r \phi_i} |\nabla_g w|^2 \, d\Omega \right]_0^T
\]

\[
- \frac{1}{2} \int_{\Omega} \left[ \nabla_g w \right]_{g}^2 \frac{d}{dt} (e^{r \phi_i}) \, dQ. \tag{4.2.11}
\]

Next, after (4.2.8) has been integrated over [0, \( T \)], we insert (4.2.10) and (4.2.11) into it and obtain (4.2.7), as desired.

Finally, we combine the L.H.S. = (4.2.3) with the R.H.S. = (4.2.7), and we thus obtain (4.2.1). The proof of Proposition 4.2.1 is complete. \( \square \)

**Step 2.** The following lemma will be invoked repeatedly for various suitable choices of the function \( m(x, t) \). It is the counterpart of [17, Lemma 2.2.2].

**Lemma 4.2.2.** Let \( w \) be a solution of (3.7) in the class (3.8). Let \( m(x, t) \) be a \( C^1 \)-function defined over \( \Omega \). Then the following identity holds true,

\[
\int_{\Omega} \left( \frac{1}{2} |\nabla_g w|^2 \right) m \, dQ = \int_{\Omega} \langle \nabla_g w, \nabla_g m \rangle_g \, dQ - \int_{\Omega} w m \, dQ
\]

\[
- \int_{\Omega} \left[ F_i(w) + f \right] w m \, dQ + \left[ \int_{\Omega} w m \, dQ \right]_0^T
\]

\[
- \int_{\Sigma} w m \frac{\partial w}{\partial \nu_{\Sigma}} \, d\Sigma. \tag{4.2.12}
\]

**Proof.** We multiply both sides of (3.7) by \( w m \) and integrate by parts, invoking the Green formula (4.1.1). This way, (4.2.12) is obtained. \( \square \)

**Proposition 4.2.3.** Let \( w \) be a solution of (3.7) in the class (3.8). Then the following identity holds true,

\[
\int_{\Sigma} e^{r \phi_i} \left[ h(w) - \phi_i w_i \right] \frac{\partial w}{\partial \nu_{\Sigma}} \, d\Sigma + \frac{1}{2} \int_{\Sigma} w \mu \frac{\partial w}{\partial \nu_{\Sigma}} \, d\Sigma
\]
\[ + \frac{1}{2} \int_{\Omega} e^{\tau \phi} \left[ w_t^2 - |\nabla_g w|^2 \right] h \cdot v \, d\Sigma \]
\[ = \int_{Q} e^{\tau \phi} D^2 \phi(\nabla_g w, \nabla_g w) \, dQ - 2c \int_{Q} e^{\tau \phi} w_t^2 \, dQ \]
\[ + \tau \int_{Q} e^{\tau \phi} \left[ h(w) - w_t \phi_t \right]^2 \, dQ + \frac{1}{2} \int_{Q} w(\nabla_g w, \nabla_g \mu)_{g} \, dQ \]
\[ - \frac{1}{2} \int_{Q} w w_t \mu_t \, dQ - \frac{1}{2} \int_{Q} \left[ F_1(w) + f \right] w \mu \, dQ \]
\[ - \int_{Q} \left[ F_2(w) + f \right] e^{\tau \phi} \left[ h(w) - \phi_t w_t \right] \, dQ + \left[ \alpha(t) \right]^T_0. \tag{4.2.13} \]

where \( h(w) = \langle \nabla_g w, h \rangle_g \) by (2.11), \( D^2 \phi(\cdot, \cdot) \) is the Hessian of \( \phi \) (see (2.25)), and where we have set

\[ \mu(x, t) = \text{div}_0(e^{\tau \phi} h) - \frac{d}{dt}(e^{\tau \phi} h) \]
\[ = e^{\tau \phi} \left[ \tau |\nabla_g \phi|^2 - \tau \phi_t^2 - \alpha \phi + 2c \right]; \tag{4.2.14} \]
\[ \alpha(t) = \int_{\Omega} e^{\tau \phi} w_t \left[ h(w) - \frac{1}{2} \phi_t w_t \right] \, d\Omega \]
\[ - \frac{1}{2} \int_{\Omega} e^{\tau \phi} |\nabla_g w|^2 \, d\Omega + \frac{1}{2} \int_{\Omega} w \mu \, d\Omega. \tag{4.2.15} \]

**Proof.** We apply Lemma 4.2.2 with the choice \( m = \mu \) in (4.2.14), and obtain from (4.2.12),

\[ \frac{1}{2} \int_{Q} w_t^2 - |\nabla_g w|^2 \, \text{div}_0(e^{\tau \phi} h) \, dQ \]
\[ = \frac{1}{2} \int_{Q} \left[ w_t^2 - |\nabla_g w|^2 \right] \frac{d}{dt}(e^{\tau \phi} h) \, dQ + \frac{1}{2} \int_{Q} w (\nabla_g w, \nabla_g \mu)_{g} \, dQ \]
\[ - \frac{1}{2} \int_{Q} w w_t \mu_t \, dQ - \frac{1}{2} \int_{Q} \left[ F_1(w) + f \right] w \mu \, dQ \]
\[ + \frac{1}{2} \left[ \int_{\Omega} w w_t \mu \, d\Omega \right]^T - \frac{1}{2} \int_{\Omega} w \mu \frac{\partial w}{\partial \nu_g} \, d\Sigma. \tag{4.2.16} \]
Inserting (4.2.16) into the right-hand side of (4.2.1), to replace the second integral term over $Q$, yields after a cancellation,

$$
\int_{\Sigma} e^{t\phi} \left[ h(w) - \phi_t w_t \right] \frac{\partial w}{\partial \nu} d\Sigma + \frac{1}{2} \int_{\Sigma} e^{t\phi} \left[ w_t^2 - |\nabla_g w|^2 \right] h \cdot \nu \, d\Sigma
+ \frac{1}{2} \int_{\Sigma} w \mu \frac{\partial w}{\partial \nu} d\Sigma
= \int_{Q} e^{t\phi} D^2 \phi (\nabla_g w, \nabla_g w) \, dQ + \int_{Q} w_t^2 \frac{d}{dt} (e^{t\phi} \phi_t) \, dQ
+ \frac{1}{2} \int_{Q} w \langle \nabla_g w, \nabla_g \mu \rangle \, dQ - \frac{1}{2} \int_{Q} w w_t \mu_t \, dQ
+ \tau \int_{Q} e^{t\phi} \left[ |h(w)|^2 \right] dQ - 2\tau \int_{Q} e^{t\phi} h(w) \phi_t w_t \, dQ
+ \frac{1}{2} \left[ \int_{\Omega} w w_t \mu \, d\Omega \right]^T_0 + \left[ \int_{\Omega} e^{t\phi} \left[ h(w) - \frac{1}{2} \phi_t w_t \right] w_t \, d\Omega \right]^T_0
- \frac{1}{2} \left[ \int_{\Omega} e^{t\phi} \phi_t \nabla_g w_t \nabla_g w \, d\Omega \right]^T_0 - \frac{1}{2} \int_{Q} [F_1(w) + f] w \mu \, dQ
- \int_{Q} [F_1(w) + f] e^{t\phi} \left[ h(w) - w_t \phi_t \right] \, dQ. \tag{4.2.17}
$$

We next combine the second, the fifth, and the sixth term on the right-hand side of (4.2.17) in a perfect square,

$$
\int_{Q} w_t^2 \frac{d}{dt} (e^{t\phi} \phi_t) \, dQ - 2\tau \int_{Q} e^{t\phi} \phi_t w_t h(w) \, dQ + \tau \int_{Q} e^{t\phi} \left[ |h(w)|^2 \right] dQ
= \tau \int_{Q} e^{t\phi} \left[ h(w) - \phi_t w_t \right]^2 \, dQ - 2c \int_{Q} e^{t\phi} w_t^2 \, dQ, \tag{4.2.18}
$$

expanding $\frac{d}{dt} (e^{t\phi} \phi_t) = e^{t\phi} [\tau \phi_t^2 + \phi_t] = e^{t\phi} [\tau \phi_t^2 - 2c]$, see (3.6e). Using (4.2.18) into the right-hand side of (4.2.17) yields (4.2.13) via (4.2.15), as desired.

The following result is the counterpart of [17, Theorem 2.2.4].
Step 3

**Theorem 4.2.4 (Final identity).** Let \( w \) be a solution of (3.7) in the class (3.8). Then the following identity holds true,

\[
\left( BT_w \right)_{|\Sigma} = \int_Q e^{r\phi} D^2 \phi (\nabla_s w, \nabla_s w) \, dQ - 2 \rho \int_Q e^{r\phi} |\nabla_s w|^2 \, dQ \\
+ (\rho - c) \int_Q e^{r\phi} \left[ |\nabla_s w|^2 + w_t^2 \right] \, dQ + \tau \int_Q e^{r\phi} \left[ h(w) - \phi_t w_t \right]^2 \, dQ \\
+ \int_Q \left[ (\rho + c) \frac{d}{dt} (e^{r\phi}) - \frac{1}{2} \mu \right] \, dQ \\
+ \int_Q \left[ \nabla_s w_t - \frac{1}{2} \nabla_s \mu - (\rho + c) \nabla_s (e^{r\phi}) \right] \, dQ \\
+ \int_Q \left[ F_1(w) + f \right] \left[ (\rho + c) e^{r\phi} - \frac{1}{2} \mu \right] \, dQ \\
- \int_Q \left[ F_1(w) + f \right] e^{r\phi} \left[ h(w) - \phi_t w_t \right] \, dQ + \beta(t) |_{\partial \Omega},
\]

where \( \mu \) is defined by (4.2.14). Moreover, the boundary term \( (BT_w)_{|\Sigma} \) is given by

\[
\left( BT_w \right)_{|\Sigma} = \int_{\Sigma} e^{r\phi} \left[ h(w) - \phi_t w_t \right] \frac{\partial w}{\partial \nu_{\partial \Sigma}} \, d\Sigma \\
+ \int_{\Sigma} \frac{\partial w}{\partial \nu_{\partial \Sigma}} \left[ \frac{1}{2} \mu - (\rho + c) e^{r\phi} \right] \, d\Sigma \\
+ \frac{1}{2} \int_{\Sigma} e^{r\phi} \left[ w_t^2 - |\nabla_s w|^2 \right] h \cdot \nu \, d\Sigma,
\]

and \( \beta(t) \) is defined by

\[
\beta(t) = \alpha(t) - (\rho + c) \int_{\Omega} e^{r\phi} w_t w \, d\Omega,
\]

where \( \alpha(t) \) is defined in (4.2.15).
Proof. We return to the first two integral terms in $Q$ on the right-hand side of identity (4.2.13) and rewrite them, after adding and subtracting, as

\[
\int_Q e^{\tau\phi}D^2\psi(\nabla_x w, \nabla_x w) \, dQ - 2c \int_Q e^{\tau\phi}w_t^2 \, dQ
\]

\[
= \int_Q e^{\tau\phi}D^2\psi(\nabla_x w, \nabla_x w) \, dQ - 2\rho \int_Q e^{\tau\phi}|\nabla_x w|^2 \, dQ
\]

\[
+ 2\rho \int_Q e^{\tau\phi}|\nabla_x w|^2 \, dQ - 2c \int_Q e^{\tau\phi}w_t^2 \, dQ
\]

\[
= \int_Q e^{\tau\phi}D^2\psi(\nabla_x w, \nabla_x w) \, dQ - 2\rho \int_Q e^{\tau\phi}|\nabla_x w|^2 \, dQ
\]

\[
+ (\rho - c) \int_Q e^{\tau\phi}|\nabla_x w|^2 \, dQ + (\rho - c) \int_Q e^{\tau\phi}w_t^2 \, dQ
\]

\[
+ (\rho + c) \int_Q e^{\tau\phi}[|\nabla_x w|^2 - w_t^2] \, dQ. \quad (4.2.22)
\]

Next, we apply Lemma 4.2.2, (4.2.12), with the choice $m = e^{\tau\phi}$, and obtain

\[
\int_Q e^{\tau\phi}[|\nabla_x w|^2 - w_t^2] \, dQ
\]

\[
= \int_Q w_t \frac{d}{dt} (e^{\tau\phi}) \, dQ - \int_Q w \langle \nabla_x w, \nabla_x (e^{\tau\phi}) \rangle \, dQ + \int_{\Sigma} \frac{\partial w}{\partial \nu_x} we^{\tau\phi} \, d\Sigma
\]

\[
- \left[ \int_Q w e^{\tau\phi} \, d\Omega \right]_0^T + \int_Q \left[ F_1(w) + f \right]we^{\tau\phi} \, dQ. \quad (4.2.23)
\]

We then use (4.2.23) into the last term of (4.2.22) after inserting (4.2.22) into (4.2.13) and obtain (4.2.19).

Step 4. Henceforth, we concentrate our analysis on the right-hand side (R.H.S.) of the fundamental identity (4.2.19) of Theorem 4.2.4. So far, the parameter $\tau > 0$ has been arbitrary. The next lemma and its proof show the key virtue of the free parameter $\tau$ entering the present multiplier (4.2.2) in dealing with the general first-order differential operator $F_1(w)$ as in (1.3): choosing $\tau$ sufficiently large permits the absorption of a bad energy level term, which arises precisely because $F_1(w)$ is of order 1.

Lemma 4.2.5. Let $w$ be a solution of (3.7) in the class (3.8). With reference to some selected terms on the right-hand side of identity (4.2.19), we
have:

(i) For any $\varepsilon > 0$, we have, recalling (1.3) and $h(w) = \langle h, \nabla w \rangle_g$ with $h = \nabla \phi$,

$$
\tau \int_Q e^{\varepsilon \phi}[h(w) - \phi_i w_i]^2 dQ - \int_Q \left[ F_1(w) + f \right] e^{\varepsilon \phi}[h(w) - \phi_i w_i] dQ
\geq \left( \tau - \frac{C_T}{2\varepsilon} \right) \int_Q e^{\varepsilon \phi}[h(w) - \phi_i w_i]^2 dQ
- \frac{\varepsilon}{2} \int_Q \left[ w_i^2 + |\nabla g|^2_g + w^2 + f^2 \right] e^{\varepsilon \phi} dQ,
$$

(4.2.24)

where $C_T$ is the constant in (1.3).

(ii) Next, for any $\varepsilon > 0$, we have

$$
\int_Q \left[ (\rho + c) \frac{d(e^{\varepsilon \phi})}{dt} - \frac{1}{2} \mu \right] dQ
+ \int_Q \left[ e^{\varepsilon \phi} \nabla_g \left[ \frac{1}{2} \mu - (\rho + c)e^{\varepsilon \phi} \right] \right] dQ
+ \int_Q \left[ F_1(w) + f \right] w \left[ (\rho + c)e^{\varepsilon \phi} - \frac{1}{2} \mu \right] dQ
\geq - \frac{\varepsilon}{2} \int_Q e^{\varepsilon \phi} \left[ w_i^2 + |\nabla g|^2_g + f^2 \right] dQ - \frac{T \text{const}}{2\varepsilon} \|w\|_{C^{1,2}(0,T; L^2(\Omega))}^2,
$$

(4.2.25)

where $\text{const}_T$ is a constant depending on $\tau$.

(iii) Furthermore, recalling (4.2.21) and (4.2.15), we have

$$
|\beta(t)|_{0,T}^\tau \leq C(1 + \tau) e^{-\delta \tau} \left[ E(0) + E(T) + \|w\|_{C^{1,2}(0,T; L^2(\Omega))}^2 \right],
$$

(4.2.26)

where the constant $C$ is independent of $T$ or $\tau$, and where $E(\cdot)$ is defined in (3.11).

Proof. For both (i) and (ii), we use the inequality $2ab \leq \varepsilon a^2 + (1/\varepsilon)b^2$, where $a$ denotes “energy terms” $w_i, |\nabla_g w|^2_g, F_1(w)$, while $b$ denotes the “lower-order terms” (i.e., $w$). Here, we recall (1.3) for $F_1(w)$ as well as (4.2.14) for $\mu$ and (3.6e).

(iii) Here we use (3.6c) in estimating $\alpha(t)$ and $\beta(t)$ in (4.2.15) and (4.2.21); see also (4.2.14) for $\mu$. 

Remark 4.2.1. In the second integral over $Q$ on the left-hand side of (4.2.24), both factors $F_2(w)$ and $[h(w) - \phi_i w_i', h(w) = \langle h, \nabla_g w \rangle_g$ by (2.11), are energy levels, when $F_2$ is a general first-order operator. The virtue of the free parameter $\tau$ is seen in the first term on the right-hand side of (4.2.24), in making the coefficient $\tau - (C_T/2\epsilon) > 0$ after $\epsilon > 0$ has been fixed, and dropping that term; see next result.

Step 5. We complete the proof of Theorem 3.3. As explained in Remark 4.2.1, with $\epsilon > 0$ given in Lemma 4.2.5, we select the parameter $\tau$ as $\tau = C_T/\epsilon$ so that $\tau - C_T/2\epsilon = C_T/2\epsilon > 0$, drop the first term on the R.H.S. of (4.2.24), then use the remaining version of inequality (4.2.24) along with (4.2.25) in the R.H.S. of identity (4.2.19). We obtain

$$
(BT_w)|x + T \frac{\text{const}}{2\epsilon} ||w||_{C([0,T]; L^2(\Omega))}^2 + \epsilon \int_Q e^{\tau \Phi} f^2 \, dQ
\geq \int_Q e^{\tau \Phi} D^2 \phi(\nabla_g w, \nabla_g w) \, dQ - 2 \rho \int_Q e^{\tau \Phi} |\nabla_g w|_g^2 \, dQ
+ (\rho - \sigma - \epsilon) \int_Q e^{\tau \Phi} \left[ |\nabla_g w|_g^2 + w_i^2 \right] \, dQ - \left| \left[ \beta(t) \right]_0 \right|. \tag{4.2.27}
$$

Next, we invoke assumption (H.3), in the form of (3.2b), so that the first two terms on the R.H.S. of (4.2.27) vanish; moreover, we recall (4.2.26) for $[\beta(t)]_0$, and thus obtain the desired inequality (3.9a) from (4.2.27), where $\epsilon = C_T/\tau$. Then, inequality (3.9a) yields (3.9b), by recalling property (3.6d) of $\phi$. Theorem 3.3 is proved.

5. PROOF OF THEOREM 3.4: CARLEMAN ESTIMATES (SECOND VERSION); AND OF THEOREM 3.1 (DIRICHLET CASE)

5.1. Proof of Theorem 3.4

Having already established (3.9) of Theorem 3.3, as proved in Section 4, we obtain then (3.14) of Theorem 3.4, by simply using in the integral $\int_0^T E(t) \, dt$ on the R.H.S. of (3.9b) the inequality

$$
E(t) \geq \frac{E(0) + E(T)}{2} e^{-C_T t} - \Lambda(T), \quad 0 \leq t \leq T, \tag{5.1.1}
$$

$$
\Lambda(T) = \int_0^T \int_\Omega f^2 \, dQ + 2 \int_0^T \int_T \left| \frac{\partial w}{\partial \nu} \right|^2 \, d\Sigma + C_T \int_0^T ||w||^2_{L^2(\Omega)} \, dt. \tag{5.1.2}
$$
But all this follows directly from [17, Lemma 2.3.1], which yields, for $T \geq t \geq s \geq 0$,

\begin{align}
E(t) &\leq [E(s) + \Lambda(T)]e^{C_T(t-s)}, \\
E(s) &\leq [E(t) + \Lambda(T)]e^{C_T(t-s)},
\end{align}

(5.1.3)

in its proof [17, eqn. (2.3.6)]. Next, the inequality on the right of (5.1.3) with $s = 0$, and that on the left with $t = T$ and $s = t$, yield then

\begin{align}
E(0) &\leq [E(t) + \Lambda(T)]e^{C_T}, \\
E(T) &\leq [E(t) + \Lambda(T)]e^{C_T T}.
\end{align}

(5.1.4)

Summing up these two inequalities in (5.1.4), we arrive at (5.1.1), as desired.

Thus, using (5.1.1) into the integral over $[t_0, t_1]$ on the R.H.S. of (3.9b), we obtain

\begin{align}
(BT_w)\Sigma + \left[\frac{C_T}{\tau} + \left(\rho - c - \frac{C_T}{\tau}\right)e^{-\left(\frac{\tau}{2}\right)}(t_1 - t_0)\right] &\int_Q f^2 \,dQ \\
+ 2\int_0^T \int_{\Gamma} \left(\frac{\partial w}{\partial \nu}\right) \,d\Sigma + TC_T \text{const}\|w\|_{C^0[0,T]; L^2(\Omega)}
\end{align}

\begin{align}
\geq e^{-\left(\frac{\tau}{2}\right)}\left(\rho - c - \frac{C_T}{\tau}\right)\left(\frac{t_1 - t_0}{2}\right)e^{-C_T T}
\end{align}

\begin{align}
&\quad -C(1 + \tau)e^{-\left(\frac{\tau}{2}\right)/2}\left[|E(T) + E(0)|\right],
\end{align}

(5.1.5)

from which (3.14) of Theorem 3.4 is obtained, via (3.16). The proof of Theorem 3.4 is complete. □

5.2. Proof of Theorem 3.1 (Dirichlet Case)

Let $\psi$ be a solution of the $\psi$-problem in (1.4) (including the B.C. $\psi|_\Sigma = 0$). We want to apply Theorem 3.4 to it.

Step 1. First, we deal with the values of $|\nabla \psi|^2_{\Sigma}$ and $h(\psi)$ on the boundary $\Gamma$, respectively, as required by $(BT_w)|_\Sigma$ in (3.10).

Lemma 5.2.1. Let $\psi$ be the solution of problem (1.4) [including the B.C. $\psi|_\Sigma = 0$]. Then, in this case, the boundary term $(BT_\psi)|_\Sigma$ defined by (3.16) and (3.10) reduces to

\begin{align}
(BT_\psi)|_\Sigma = (BT_\psi)|_\Sigma = \frac{1}{2} \int_\Sigma e^{-\phi} \left(\frac{\partial \psi}{\partial \nu}\right)^2 \frac{h \cdot \nu}{|\nu|^2} \,d\Sigma,
\end{align}

(5.2.1)
where, via (2.5), we define $\nu_\omega(x)$,
\begin{equation}
\nu_\omega(x) = \sum_{i=1}^{n} \left( \sum_{j=1}^{n} a_{ij}(x) \nu_j(x) \right) \frac{\partial}{\partial x_i} = A(x) \nu(x), \tag{5.2.2}
\end{equation}
to be the normal of the submanifold $\Gamma$ in the Riemannian metric $g$.

Proof. Given $x \in \mathbb{R}^n$, the vector $\nabla_g \psi(x)$ has the decomposition into direct product in $(\mathbb{R}^n, g(x))$ as
\begin{equation}
\nabla_g \psi(x) = \left( \nabla_g \psi(x), \frac{\nu_\omega}{|\nu_\omega|_g} \right) \frac{\nu_\omega}{|\nu_\omega|_g} + Y(x)
= \left( \frac{1}{|\nu_\omega|_g^2} \frac{\partial \psi}{\partial \nu_\omega} \right) \nu_\omega + \frac{\partial \psi}{\partial s}. \tag{5.2.3}
\end{equation}
Here, by (5.2.2), (2.9), and (2.12),
\begin{equation}
\langle \nabla_g \psi(x), \nu_\omega(\cdot) \rangle_g = \langle \nabla_g \psi(x), A(x) \nu(\cdot) \rangle_g
= \nabla_g \psi(x) \cdot \nu(x) = \frac{\partial \psi}{\partial \nu_\omega}. \tag{5.2.4a}
\end{equation}
Moreover, $Y(x) \in \mathbb{R}^n$ satisfies $\langle Y(x), \nu_\omega \rangle_g = 0$; consequently, by (2.9) and (5.2.2), $Y(x) \cdot \nu(x) = \langle Y(x), \nu_\omega(\cdot) \rangle_g = 0$, that is, $Y(x) \in T_x \Gamma$, the tangent space of $\Gamma$ at $x$. Therefore, if $s$ denotes a unit tangent vector, then, by (2.11),
\begin{equation}
Y(x) = \langle \nabla_g \psi(x), s \rangle_g = \nabla_0 \psi(x) \cdot s = \frac{\partial \psi(x)}{\partial s} \tag{5.2.4b}
\end{equation}
is the tangential gradient. Thus, (5.2.4a–b) show the R.H.S. of (5.2.3). By (5.2.3) and (2.11), we have
\begin{equation}
|\nabla_g \psi|_g^2 = \langle \nabla_g \psi, \nabla_g \psi \rangle_g = \nabla_g \psi(\cdot) = \frac{1}{|\nu_\omega(\cdot)|_g^2} \langle \nabla_g \psi(\cdot), \nu_\omega(\cdot) \rangle_g^2 + Y(\psi) \tag{5.2.5a}
\end{equation}
\begin{equation}
= \frac{1}{|\nu_\omega(\cdot)|_g^2} \left( \frac{\partial \psi}{\partial \nu_\omega} \right)^2, \tag{5.2.5b}
\end{equation}
since $\psi|_S = 0$, hence $\nabla_0 \psi \perp \Gamma$ and hence $Y(\psi) = \nabla_0 \psi \cdot Y = 0$ by (2.11). Similarly, $h(x)$ has the decomposition into direct product
\begin{equation}
h(x) = \left( h(x), \frac{\nu_\omega(x)}{|\nu_\omega(x)|_g} \right) \frac{\nu_\omega(x)}{|\nu_\omega(x)|_g} + Z(x), \tag{5.2.6}
\end{equation}
where \( Z(x) \in \Gamma \). Moreover, by (5.2.2), (2.12), and (2.11), we have
\[
\frac{\partial \psi}{\partial \nu} = (A(x) \nabla_0 \psi) \cdot \nu(x) = \nabla_0 \psi \cdot A(x) \nu(x) = \nabla_0 \psi \cdot \nu_\delta(x)
\]
\[
= \langle \nabla_0 \psi, \nu_\delta \rangle_g, \tag{5.2.7}
\]
since the matrix \( A(x) \) is symmetric. Hence, by (2.11), (5.2.2), (5.2.6), (5.2.7), and (2.9),
\[
h(\psi)(x) = \langle \nabla_0 \psi, h \rangle_g
\]
\[
= \left( \frac{\partial \psi}{\partial \nu} \right) \left( \frac{\nu_\delta(x)}{|\nu_\delta(x)|_g^2} \right) \langle \nabla_0 \psi, \nu_\delta(x) \rangle_g + \langle \nabla_0 \psi, Z(x) \rangle_g, \tag{5.2.8}
\]
\[
h(\psi)(x) = \frac{\langle \nabla_0 \psi, \nu_\delta(x) \rangle_g}{|\nu_\delta(x)|_g^2} \left( \frac{\partial \psi}{\partial \nu} \right) = \frac{\langle h(x), A(x) \nu(x) \rangle_g}{|\nu_\delta(x)|_g^2} \frac{\partial \psi}{\partial \nu_\delta},
\]
(by (2.9))
\[
= \frac{h(x) \cdot \nu(x)}{|\nu_\delta(x)|_g^2} \left( \frac{\partial \psi}{\partial \nu} \right), \tag{5.2.9}
\]
since, as before, \( \psi|_\Sigma = 0 \), hence, \( \nabla_0 \psi \perp \Gamma \), and \( \langle \nabla_0 \psi, Z \rangle_g = \nabla_0 \psi \cdot Z = 0 \), via (2.11).

Finally, we return to definition (3.10) for \( BT|_\Sigma \) (written for \( \psi \)); use here \( \psi|_\Sigma = 0 \), hence \( \psi_t = 0 \), as well as (5.2.5) and (5.2.9), to obtain
\[
(BT)_t|_\Sigma = \int \Sigma e^{\tau \phi} \left( \frac{\partial \psi}{\partial \nu} \right) h(\psi) d\Sigma - \frac{1}{2} \int \Sigma e^{\tau \phi} |\nabla_0 \psi|_g^2 h \cdot \nu d\Sigma \tag{5.2.10}
\]
\[
= \int \Sigma e^{\tau \phi} \left( \frac{\partial \psi}{\partial \nu} \right)^2 \frac{h \cdot \nu}{|\nu_\delta(x)|_g^2} d\Sigma - \frac{1}{2} \int \Sigma e^{\tau \phi} \left( \frac{\partial \psi}{\partial \nu_\delta} \right)^2 \frac{h \cdot \nu}{|\nu_\delta(x)|_g^2} d\Sigma. \tag{5.2.11}
\]
Then, (5.2.11) yields (5.2.1), as desired. \( \blacksquare \)

**Step 2. Completion of the Proof of Theorem 3.1.** In the Dirichlet case, to obtain the continuous observability inequality (1.5) from inequality (3.15) of Theorem 3.4 already proved, it suffices to return to (5.2.1); since \( h(x) \cdot \nu(x) \leq 0 \) for \( x \in \Gamma_0 \) by assumption, we readily have from (5.2.1),
\[
\frac{1}{2} \max_{\substack{x \in \Gamma_1 \\ 0 < t < T}} \left( e^{\tau \phi} \frac{h(x) \cdot \nu(x)}{|\nu_\delta(x)|_g^2} \right) \int_0^T \left( \frac{\partial \psi}{\partial \nu_\delta} \right)^2 d\Sigma \geq (BT)_t|_\Sigma. \tag{5.2.12}
\]
Then (5.2.12) used on the left-hand side of inequality (3.15) yields (when the parameter \( \tau > 0 \) is large enough and \( f \equiv 0 \),

\[
\int_0^T \int T \left( \frac{\partial \psi}{\partial \nu} \right)^2 d\Sigma + k_2 \| \psi \|^2_{L^2(0,T;L^2(\Omega))} \geq k_1 E(0), \tag{5.2.13}
\]

where \( k_1, k_2 > 0 \) are constants.

To get the sought-after inequality (1.5) from (5.2.13), we only need to drop the low-order term \( k_2 \| \psi \|^2_{L^2(0,T;L^2(\Omega))} \) in (5.2.13). This may be done, as usual, by a compactness/uniqueness argument \([19, 14] \); see Remark 3.1.

6. PROOF OF THEOREM 3.5: MAIN INVERSE INEQUALITY

We prove the specialized version of Theorem 3.5 for \( w \) solution of (3.7) within the class (3.8), which moreover satisfies hypothesis (3.17).

Step 1

**Lemma 6.1.** Let \( w \) solve (3.7) and satisfy (3.17): \( w|_{\Sigma_0} = 0 \) and \( h \cdot \nu \leq 0 \) on \( \Gamma_0 \).

(a) Then, in this case, the boundary terms \((BT)_w|_\Sigma\) defined by (3.16), (3.10) reduce to

\[
(BT_w)|_\Sigma = (BT_w)|_{\Sigma_0} + (BT_w)|_{\Sigma_1};
\]

\[
(BT_w)|_{\Sigma_0} = (BT_w)|_{\Sigma_0} = \frac{1}{2} \int_0^T \int T \left( \frac{\partial w}{\partial \nu} \right)^2 d\Sigma \leq 0; \tag{6.2}
\]

\[
|(BT_w)|_{\Sigma_1} \leq C \left( \int_0^T \int T \left( \left( \frac{\partial w}{\partial s} \right)^2 + \left( \frac{\partial w}{\partial s} \right)^2 + w^2 \right) d\Sigma \right.
\]

\[
\left. + \| w \|^2_{L^2(0,T;H^{1/2,\epsilon}(\Omega))} \right) \tag{6.3}
\]

for any \( \epsilon_0 > 0 \), where \( \partial w/\partial s \) denotes, as before, the tangential gradient (derivative) of \( w \) on \( \Gamma \), so that \( (\partial w/\partial s)^2 = |\nabla_{\text{tangential}} w|^2_{0(\Omega)} \).
(b) Moreover, if in addition, \( w \) satisfies also \( (\partial w / \partial \nu_w)|_{\Sigma_1} = 0 \), then

\[
(BT_w)|_{\Sigma_1} = (BT_w)|_{\Sigma_1} = \frac{1}{2} \int_0^T \int_{\Gamma_1} e^{r_{\eta}} \left[ w_1^2 - \left( \frac{\partial w}{\partial s} \right)^2 \right] h \cdot \nu d\Sigma.
\] (6.4)

**Proof.** We return to (3.16) and (3.10); we then see that \( BT_w \) and \( BT_w \) coincide on \( \Sigma_0 = (0, T) \times \Gamma_0 \), since \( w|_{\Sigma_0} = 0 \) by assumption. We may divide \( BT_w|_{\Sigma_0} \) as in identity (6.1), where \( BT_w|_{\Sigma_0} \) is given by (6.2) by virtue of the same argument of Lemma 5.2.1 culminating in (5.2.10) and (5.2.11) carried out this time on \( \Sigma_0 \). Similarly, from (3.16) and (3.10), where \( h(w) = \langle \nabla_{\eta} v, \nabla_{\eta} w \rangle_{\eta} \), we readily obtain

\[
(BT_w)|_{\Sigma_1} = (BT_w)|_{\Sigma_1} = \frac{1}{2} \int_0^T \int_{\Gamma_1} e^{r_{\eta}} \left[ w_1^2 - |\nabla_{\eta} w|^2 \right] h \cdot \nu d\Sigma,
\]

when \( \frac{\partial w}{\partial \nu_{\eta}} |_{\Sigma_1} = 0 \); (6.5a)

\[
|BT_w|_{\Sigma_1} \leq C \left[ \int_0^T \int_{\Gamma_1} \left( \frac{\partial w}{\partial \nu_{\eta}} \right)^2 + |\nabla_{\eta} w|^2 + w_1^2 \right] d\Sigma
\]

\[
+ \left\| \frac{w}{\partial \nu_{\eta}} \right\|_{L^2(0, T; H^{1/2 + \epsilon}(\Omega))}^2, \quad \text{in general}, \ (6.5b)
\]

by use of trace theory applied to \( w \in \Gamma_1 \). Next, the decomposition \( \nabla_{\eta} w \) in normal and tangential components yields, by virtue of (5.2.5a),

\[
|\nabla_{\eta} w|^2 = \begin{cases} 
\left( \frac{\partial^2 w}{\partial s} \right)^2, & \text{when } \frac{\partial w}{\partial \nu_{\eta}} |_{\Sigma_1} = 0; \\
\frac{1}{|\nu_{\eta}(x)|^2} \left( \frac{\partial w}{\partial \nu_{\eta}} \right)^2 \left( \frac{\partial^2 w}{\partial s} \right)^2, & \text{otherwise},
\end{cases} \quad \text{(6.6a)}
\]

since, from (5.2.3), \( Y(x) \in \Gamma_\nu \), the tangent space of \( \Gamma \) at \( x \), we have \( Y(w) = \nabla_{\eta} w \cdot Y = (\partial w / \partial s)^2 \) by (2.11), (5.2.4b). Then, (6.6a) and (6.6b), used in (6.5a) and (6.5b), yield (6.4) and (6.3), respectively. Lemma 6.1 is proved. ■

**Step 2.** The following result is taken from [15, Section 7.2]. It is proved by micro-local analysis. It is critical in eliminating artificial geometrical
conditions of the earlier literature on the controlled part $\Gamma_1$ of the boundary in the Neumann case.

**Lemma 6.2.** Let $f \in L^2(Q)$ and let $w$ be a solution of (3.7) in the class (3.8).

(a) Then, for any $\epsilon > 0$, $\epsilon_0 > 0$, and $T > 0$, there exists a constant $C_{\epsilon, \epsilon_0, T} > 0$ such that

$$
\int_\epsilon^T \int_{\Gamma_1} \left( \frac{\partial w}{\partial \nu} \right)^2 d\Sigma \leq C_{\epsilon, \epsilon_0, T} \left( \int_0^T \int_{\Gamma_1} \left( \frac{\partial w}{\partial \nu_\epsilon} \right)^2 + w_\epsilon^2 \right) d\Sigma
$$

$$
+ \|w\|_{L^2(0, T; H^{1/2, \epsilon}(\Omega))}^2 + \|f\|_{L^2(Q)}^2.
\tag{6.7}
$$

(b) Moreover, if $w$ satisfies in addition hypothesis (3.17): $w|_{\Sigma_0} = 0$ and $h \cdot v \leq 0$ on $\Gamma_0$, then inequality (6.7) holds true with $\Gamma$ replaced by $\Gamma_1$.

**Step 4.** We next use Lemma 6.2, (6.7) to eliminate the tangential derivative from the estimate (6.3) [or identity (6.4)] of the boundary terms $(BT_w)$ evaluated over $[\epsilon, T - \epsilon] \times \Gamma_1$.

**Proposition 6.3.** Let $f \in L^2(Q)$ and let $w$ be a solution of (3.7) in the class (3.8). Moreover, let $w$ satisfy hypothesis (3.17). Then, for all $\tau > 0$ sufficiently large, there exists a constant $k_{\phi, \tau} > 0$ such that

$$
\int_\epsilon^T \int_{\Gamma_1} \left( \frac{\partial w}{\partial \nu_\epsilon} \right)^2 + w_\epsilon^2 \right) d\Sigma + \frac{C_\tau}{\tau} \int_Q e^{r_\phi} f^2 \, dQ + C_\tau \|w\|_{L^2(0, T; H^{1/2, \epsilon}(\Omega))}^2
\geq k_{\phi, \tau} \left( E(T) + E(0) \right).
\tag{6.8}
$$

**Proof.** We apply Theorem 3.4, estimate (3.15), over $[\epsilon, T - \epsilon] \times \Gamma$ rather than $[0, T] \times \Gamma = \Sigma$. In so doing, we use hypothesis (3.17) to invoke (6.2) and conclude that $(BT_w)|_{[\epsilon, T - \epsilon] \times \Gamma_0} \leq 0$. Moreover, we invoke (6.3) for $(BT_w)|_{[\epsilon, T - \epsilon] \times \Gamma_1}$ and use the key estimate (6.7). Finally, the right-hand side of (3.15) becomes $k_{\phi, \tau} [E(\epsilon) + E(T - \epsilon)]$. But

$$
E(\epsilon) + E(T - \epsilon) \geq [E(0) + E(T)] e^{-C_\tau \epsilon} - 2\Lambda(T).
\tag{6.9}
$$

This can be proved as in the case of (5.1.1): by using the inequality on the right-hand side of (5.1.3) with $s = 0$ and $t = \epsilon$, and the inequality on the left-hand side of (5.1.3) with $t = T$ and $s = T - \epsilon$, and summing up the resulting inequalities. This yields (6.9). Then (6.8) is obtained.
Step 5. Completion of the proof of Theorem 3.5. The sought-after inequality (3.18) of Theorem 3.5 now follows at once from (6.8) of Proposition 6.3, by further majorizing its left-hand side. Theorem 3.5 is proved.

7. PROOF OF THEOREM 3.2: NEUMANN CASE

We return to inequality (3.18) of Theorem 3.5(b), written for the solution \( w = \psi \) of problem (1.7), with the boundary integral over \( \Gamma_1 \), since by assumption (3.17) holds true: \( \psi \big|_{\Sigma_1} = 0 \) and \( h \cdot \nu \leq 0 \) on \( \Gamma_0 \). Moreover, on \( \Sigma_1 \), it suffices to take \( \beta = 0 \) in (1.7), i.e., \( \partial \psi / \partial \nu \big|_{\Sigma_1} = 0 \). Then, as \( f = 0 \), (3.18) becomes the inequality

\[
\int_{\Sigma_1} \psi_i^2 d\Sigma + k_1 \| \psi \|_{C([0, T]; H^{1/2}, \mathbb{R}(\Omega))}^2 \geq k_2 E(0),
\]

where \( k_1, k_2 > 0 \) are constants. Finally, by a compactness/uniqueness argument again, see Remark 3.1, we obtain the desired inequality in (1.8).

Remark 7.1. Given the \( \psi \)-problem (1.7), say with \( \beta = 0 \), the proof of Theorem 3.5 uses (6.4) and (6.5a), (6.6a) rather than (6.3) and (6.5b), (6.6b), a streamlined procedure.

8. SOME ILLUSTRATIONS WHERE ASSUMPTIONS (H.1) AND (H.3) ON \( \mathcal{A} \) HOLD TRUE

Example 8.1. Let \( \Omega \subset \mathbb{R}^2 \) be a bounded domain. Assume that \( \mathcal{A} \) is defined by

\[
\mathcal{A}u = \frac{\partial}{\partial x} \left( \frac{1 + y^6}{1 + x^2 + y^6} \frac{\partial u}{\partial x} \right) + \frac{\partial}{\partial x} \left( \frac{xy^3}{1 + x^2 + y^6} \frac{\partial u}{\partial y} \right) \\
+ \frac{\partial}{\partial y} \left( \frac{xy^3}{1 + x^2 + y^6} \frac{\partial u}{\partial x} \right) + \frac{\partial}{\partial y} \left( \frac{1 + x^2}{1 + x^2 + y^6} \frac{\partial u}{\partial y} \right).
\]

Set

\[
A(x, y) = (a_{ij}) = \begin{pmatrix}
1 + y^6 & xy^3 & 1 + x^2 + y^6 \\
1 + x^2 + y^6 & 1 + x^2 + y^6 & xy^3 \\
xy^3 & 1 + x^2 & 1 + x^2 + y^6
\end{pmatrix}.
\]
Then, \( \det A(x, y) = 1/(1 + x^2 + y^6) > 0 \), \( \forall (x, y) \in \mathbb{R}^2 \), and \( A(x, y) \) is strictly positive definite on the bounded domain \( \Omega \). Thus, assumption (H.1) is verified.

The inverse of \( A(x, y) \) is

\[
G(x, y) = (g_{ij}) = A^{-1}(x, y) = \begin{pmatrix} 1 + x^2 & -xy^3 \\ -xy^3 & 1 + y^6 \end{pmatrix}.
\] (8.3)

Consider the Riemannian manifold \( (\mathbb{R}^2, g) \), where the Riemannian metric \( g \) is defined in the natural coordinate system \( (x, y) \) via (8.3) by

\[
g = (1 + x^2) \, dx \, dx - xy^3 \, dx \, dy - xy^3 \, dy \, dx + (1 + y^6) \, dy \, dy.
\] (8.4)

Consider the surface in \( \mathbb{R}^3 \) given by

\[
M = \left\{ (x, y, z) \mid z = f(x, y) = \frac{1}{2} x^2 - \frac{1}{4} y^4 \right\},
\]

with the induced Riemannian metric \( g_M \). Then the (projection) map \( \Phi(x, y, z) = (x, y) \), for any \( (x, y, z) \in M \), determines an isometry from \( M \) to \( (\mathbb{R}^2, g) \). The Gaussian curvature of \( (\mathbb{R}^2, g) \) at \( (x, y) \) is therefore

\[
k(x, y) = \text{the Gaussian curvature of } M \text{ at } (x, y, z)
\]

\[
= \frac{\left( \frac{\partial^2 f}{\partial x^2} \right)^2 \left( \frac{\partial^2 f}{\partial y^2} \right)^2 - \left( \frac{\partial^2 f}{\partial x \partial y} \right)^2}{\left[ 1 + \left( \frac{\partial f}{\partial x} \right)^2 + \left( \frac{\partial f}{\partial y} \right)^2 \right]^2}
\]

\[
= \frac{-3y^2}{(1 + x^2 + y^6)^2} \leq 0, \quad \forall (x, y) \in \mathbb{R}^2.
\] (8.5)

Since, by (8.5), the Gaussian curvature is non-positive, the function defined by

\[
v(x) = d^2(x, x_0), \quad x_0 \text{ fixed } \in \mathbb{R}^2,
\] (8.6)

i.e., as the square of the distance \( d(x, x_0) \), in the Riemann metric of (8.4), from \( x \) to a given fixed point \( x_0 \in \mathbb{R}^2 \), is in fact strictly convex on \( (\mathbb{R}^2, g) \) [W-S-Y, p. 108]. Thus, assumption (H.3) also holds true in this case. 

\[\blacksquare\]
Example 8.2. Let \( \Omega \subset \mathbb{R}^n \) be a bounded domain and \( a_i > 0 \) constants, \( i = 1, 2, \ldots, n \). Consider the operator on \( \mathbb{R}^n \),

\[
\mathcal{A}u = \sum_{i=1}^{n} \frac{\partial}{\partial x_i} \left( \frac{1 + \sum_{j \neq i}^{n} a_j^2 x_j^2}{1 + \sum_{k=1}^{n} a_k^2 x_k^2} \frac{\partial u}{\partial x_i} \right) - \sum_{i \neq j}^{n} \frac{\partial}{\partial x_i} \left( \frac{a_i a_j x_j}{1 + \sum_{k=1}^{n} a_k^2 x_k^2} \frac{\partial u}{\partial x_j} \right).
\]

(8.7)

Set

\[
A(x) = (a_{ij}) = \frac{1}{1 + \sum_{k=1}^{n} a_k^2 x_k^2} \begin{pmatrix}
1 + \sum_{i=2}^{n} a_i^2 x_i^2 & -a_1 a_2 x_1 x_2 & \cdots & -a_1 a_n x_1 x_n \\
-a_2 a_1 x_2 x_1 & 1 + \sum_{i=2}^{n} a_i^2 x_i^2 & \cdots & -a_2 a_n x_2 x_n \\
\vdots & \vdots & \ddots & \vdots \\
-a_n a_1 x_n x_1 & -a_n a_2 x_n x_2 & \cdots & 1 + \sum_{i=1}^{n-1} a_i^2 x_i^2
\end{pmatrix}.
\]

(8.8)

Then, the inverse of \( A(x) \) is

\[
G(x) = (g_{ij}) = A^{-1}(x) = \begin{pmatrix}
1 + a_1^2 x_1^2 & a_1 a_2 x_1 x_2 & \cdots & a_1 a_n x_1 x_n \\
a_2 a_1 x_1 x_2 & 1 + a_2^2 x_2^2 & \cdots & a_2 a_n x_2 x_n \\
\vdots & \vdots & \ddots & \vdots \\
a_n a_1 x_n x_1 & a_n a_2 x_n x_2 & \cdots & 1 + a_n^2 x_n^2
\end{pmatrix}.
\]

(8.9)

Consider the Riemannian manifold \((\mathbb{R}^n, g)\), where the Riemannian metric \( g \) is determined in the natural coordinate system \( x = (x_1, x_2, \ldots, x_n) \) via (8.8) by

\[
g = \sum_{i,j=1}^{n} g_{ij} dx_i dx_j = \sum_{i,j=1}^{n} \left( \delta_{ij} + a_i a_j x_i x_j \right) dx_i dx_j.
\]

(8.10)
where \( \delta_{ij} \) is 1 if \( i = j \), and 0 if \( i \neq j \). It follows that

\[
\sum_{i, j=1}^{n} g_{ij} \xi_i \xi_j = \sum_{i, j=1}^{n} (\delta_{ij} + a_i a_j x_i x_j) \xi_i \xi_j \geq |\xi|^2,
\]

\( \forall x, \xi = (\xi_1, \xi_2, \ldots, \xi_n) \in \mathbb{R}^n. \) \( (8.11) \)

It is easily checked from the above inequality that \((\mathbb{R}^n, g)\) is a complete non-compact Riemannian manifold.

Let \( M \) be the hypersurface in \( \mathbb{R}^{n+1} \) given by

\[
M = \left\{ [x_1, x_2, \ldots, x_n, x_{n+1}] \mid x_{n+1} = \frac{1}{2} \sum_{i=1}^{n} a_i x_i^2 \right\}, \quad (8.12)
\]

with the induced Riemannian metric in \( \mathbb{R}^n \). Then, by \([Y, \text{Lemma 3.1}]\), \( M \) is of everywhere positive sectional curvature. It is easily verified from \((8.10)\) that the map \( \Phi : M \rightarrow (\mathbb{R}^n, g) \), defined by

\[
\Phi(p) = x = [x_1, \ldots, x_n], \quad \forall p = [x_1, \ldots, x_n, x_{n+1}] \in M,
\]

is an isometry between \( M \) and \((\mathbb{R}^n, g)\). Thus, \((\mathbb{R}^n, g)\) itself is of everywhere positive sectional curvature. Since \((\mathbb{R}^n, g)\) is a non-compact, complete Riemannian manifold of everywhere positive sectional curvature, then there exists a \( C^\infty \) strictly convex function \( \nu(x) \) on \((\mathbb{R}^n, g)\) by \([G-W] \). Assumptions (H.1) and (H.3) are verified.
