We deal with the isoperimetric and the shift problem for subsets of measure 1/2 in product probability spaces. We prove that the canonical central half-spaces are extremal in particular cases: products of log-concave measures on the real line satisfying precise conditions and products of uniform measures on spheres, or balls. As a corollary, we improve the known log-Sobolev constants for Euclidean balls. We also give some new results about the related question of estimating the volume of sections of unit balls of $\ell_p^n$-sums of Minkowski spaces.

2001 Academic Press

Key Words: isoperimetry; shift; Gaussian measure; convex sets; volume.

1. INTRODUCTION

Among subsets of measure 1/2 in the unit cube $[0, 1]^n$, the half cube $[0, 1/2] \times [0, 1]^{n-1}$ has minimal boundary measure [18]. A new proof of this fact appears in [7]. It is based on the comparison of the isoperimetric function of the set $[0, 1]$ with the one of the Gaussian space. Our aim here is to extend this method to other settings: products of uniform measures on spheres, on balls, and products of log-concave measures on the real line. We will also develop a similar approach to get sharp solutions to shift problems; we will put emphasis on the formal similarities between the two questions.

Our results give a new look to the following result of Meyer and Pajor [26] about the volume of hyperplane sections of the unit balls of $\ell_p^n$. For

1 Partially supported by a grant of the Ostrowski foundation.
\[ p \in [1, \infty) \text{ and } x = (x_i)_{i=1}^n \in \mathbb{R}^n, \text{ let } \|x\|_p = \left(\sum_{i=1}^n |x_i|^p\right)^{1/p} \text{ and } |x|_\infty = \sup\{|x_i|; i = 1, \ldots, n\}. \text{ Let } B_p^n = \{x \in \mathbb{R}^n; \|x\|_p \leq 1\}. \text{ If } h \in \mathbb{R}^n \text{ is a unit vector, and } e_1 = (1, 0, \ldots, 0), \text{ then}
\]

\[
|h^+ \cap B_p^n|_n \geq |e_1^+ \cap B_p^n|_n - 1, \quad \text{for } 2 \leq p \leq \infty,
\]

\[
|h^+ \cap B_p^n|_n \leq |e_1^+ \cap B_p^n|_n - 1, \quad \text{for } 1 \leq p \leq 2.
\]

In these formulas \(|.|_n\) is the Lebesgue measure on the corresponding hyperplane. The proof of Meyer and Pajor uses the probability measures on \(\mathbb{R}^n\):

\[
d^\mu_p^n(x) = \exp(-\|x\|_p^p) \, dx.
\]

They show that

\[
\int_{h^+} e^{-\|y\|_p^p} \, d^n-1 x = \int_{e_1^+} e^{-\|y\|_p^p} \, d^n-1 x,
\]

for \(p \geq 2\) and the reverse inequality when \(p \in [1, 2]\). This means that among the sets \((h^+)_+ = \{x; (x, h) \geq 0\}\) (which have measure 1/2), the set \((e_1^+)_+\) has minimal \(\mu_p^n\)-boundary measure, for \(p \geq 2\). Our results will imply that \((e_1^+)_+\) has minimal boundary among all Borel subsets \(A\) such that \(\mu_p^n(A) = 1/2\).

We will generalize the reverse inequality for \(p \in [1, 2]\) in the following way: let \(A \subset \mathbb{R}^n\) be a smooth domain with finite boundary measure and such that \(\mu_p^n(A) = 1/2\). Denote by \(n_A(x)\) the outer normal of \(A\) at \(x\), and by \(d_{A}\) the surface measure on the boundary of \(A\). Then the Euclidean norm

\[
\left| \int_{\partial A} n_A(x) e^{-\|y\|_p^p} \, d\sigma_A(x) \right|
\]

is always less than for \(A = (e_1^+)_+\). Notice that when \(A = (h^+)_+\), the normal vector is constant: \(n_A(x) = -h\) for all \(x\) in the boundary. Thus the quantity \(\int_{\partial A} n_A(x) \exp(-\|y\|_p^p) \, d\sigma_A(x)\) is equal to the \(\mu_p^n\)-measure of the boundary of \(A\).

This work is divided into two technically independent parts. However, both of them contain statements of extremality of canonical half-spaces for product measures. The proofs follow the same pattern: a sharp comparison with the case of the Gaussian measure is established for a given probability space \((M, \mu)\). Next, this comparison is extended to the product spaces \((M^n, \mu^{\otimes n})\), and this shows the extremality of product subsets of the form \(B \times M^{n-1}\). In the first part, we compare isoperimetric and shift functionals; the tensorization devices, which allow us to go to product measures, are
Bobkov-type functional forms of the geometric inequalities. We present applications to several probability spaces: even log-concave probabilities on the real line, uniform probabilities on Euclidean spheres and on Euclidean balls. In the second part, we get more from a method of Vaaler [31]. This time, one compares the values of measures on symmetric convex sets and the tensorizing device is a result of Kanter [19] about the peaked order on unimodal measures. This tool was also the basis in [26]. We apply this method to unimodal probabilities on the real line. We complete this second part by an extension of a theorem of Meyer and Pajor about the volume of sections of $\ell_p$-sums of finite dimensional normed spaces.

As the reader will see, the two methods give quite similar results. Nevertheless, they are efficient in very different settings. The first one is convenient for the general isoperimetric problem on manifolds. For example, we solve it for sets of measure $1/2$ in a product of $k$-dimensional spheres. The second method requires a linear setting but it can be applied to non log-concave measures, where the first method would fail.

2. COMPARING ISOPERIMETRIC AND SHIFT FUNCTIONS

Let us introduce some notation. We start with the isoperimetric problem. It consists in finding subsets of prescribed measure, whose measure increases the less under enlargement. Let $(M, \rho)$ be a Riemannian manifold, let $d$ be the geodesic distance, and let $\mu$ be a probability measure on $M$. For a Borel set $A \subset M$ and for $\varepsilon > 0$, the $\varepsilon$-enlargement of $A$ is $A_\varepsilon = \{ x \in M; d(x, A) \leq \varepsilon \}$. The boundary measure of $A$ is

$$\mu^+(A) = \lim_{\varepsilon \to 0^+} \inf \frac{\mu(A_\varepsilon) - \mu(A)}{\varepsilon}.$$ 

The isoperimetric function of $(M, \mu)$ is defined for $a \in [0, 1]$ by

$$I(\mu)(a) = \inf\{ \mu^+(A); \mu(A) = a \}.$$ 

It vanishes at 0 and 1.

For convenience, we will use some rescalings to ensure that $I(\mu)(1/2) = 1$. When $\mu$ is a measure on $\mathbb{R}^n$, one defines $\mu_\lambda$ for $\lambda > 0$, by $\mu_\lambda(A) = \mu(\lambda A)$. One easily checks that $I(\mu_\lambda) = I(\mu)$. In the case of the Euclidean $n$-dimensional sphere of radius $r$, $rS^n \subset \mathbb{R}^{n+1}$, we consider the Riemannian structure induced by $\mathbb{R}^{n+1}$. Then, if $\sigma_{rS^n}$ is the uniform probability on $rS^n$, one has $I(\mu_{rS^n}) = I(\sigma_{rS^n})$.

We turn now to the shift problem. Its aim is to find the sets of given measure whose measure varies the most under translations. For references,
one can see [10]. The natural setting will be the Euclidean space \((\mathbb{R}^n, \langle \cdot , \cdot \rangle, |\cdot |)\), with a probability measure \(\mu\), with density \(\rho_\mu\) with respect to the Lebesgue measure. The shift function of \(\mu\) can be defined for \(a \in [0, 1]\) as

\[
S(\alpha) = \sup \left\{ \sup_{|h|=1} \lim_{\varepsilon \to 0^+} \frac{|\mu(A + \varepsilon h) - \mu(A)|}{\varepsilon} ; \mu(A) = a \right\}.
\]

When \(\mu\) has a smooth density \(\rho_\mu\) and \(A \subset \mathbb{R}^n\),

\[
\frac{1}{\varepsilon} \left( \mu(A + \varepsilon h) - \mu(A) \right) = \int_A \frac{\rho_\mu(y + \varepsilon h) - \rho_\mu(y)}{\varepsilon} \, dy
\]
tends to \(\int_A <\nabla \rho_\mu(y), h > \, dy\). Thus the shift function is

\[
S_\mu(\alpha) = \sup \left\{ \int_A \nabla \rho_\mu(x) \, dx ; \mu(A) = a \right\}.
\]

This makes sense in the more general case when the distributional gradient of \(\rho_\mu\) is a signed measure with density with respect to \(\mu\) [10]. Notice that when \(A\) and \(\rho_\mu\) are smooth, Green’s formula yields \(\int_A \nabla \rho_\mu(y) \, dy = \int_{\partial A} \rho_\mu n_A \, d\mathcal{A}\), where \(n_A\) is the outer normal of \(A\) and the integral is with respect to the Lebesgue measure on the boundary of \(A\). The latter quantity exists in the more general setting of embedded manifolds. So when \(\mu\) is a probability with smooth density \(\rho_\mu\) on an embedded manifold \(M \subset \mathbb{R}^k\), we can define the shift function \(S_\mu(\alpha)\), for \(a \in [0, 1]\), by

\[
S_\mu(\alpha) = \sup \left\{ \int_{\partial A} \rho_\mu(x) \, n_A(x) \, d\sigma_A(x) ; A \subset M, \mu(A) = a \right\},
\]

where the supremum is over the open sets with smooth boundary for which the integral is absolutely convergent. In the previous expression, \(n_A(x)\) is a vector of \(\mathbb{R}^k\), tangent to \(M\) and orthogonal to \(\partial A\) at \(x\), and the integral is with respect to the surface measure on \(\partial A\).

The Gaussian measure will be of particular importance in the following. Notice that we do not choose the usual convention. Let \(\gamma\) be the probability measure on \(\mathbb{R}\) with density \(\rho_\gamma(t) = \exp(-\pi t^2) \, dt\). For a measure \(\nu\) on \(\mathbb{R}\) we denote by \(R_\nu\) the distribution function \(R_\nu(t) = \nu([-\infty, t])\). The isoperimetric problem for the measures \(\gamma^{\otimes n}\) was solved in [14, 30]. The solution to the shift problem for these measures is in [20]. Half-spaces are always extremal. This remarkable property of the Gaussian measure can be stated as:

\[
I_\gamma^{\otimes n} = I_\gamma = S_\gamma = S_\gamma = \rho_\gamma \circ R_\gamma^{-1}, \quad \text{where } R_\gamma^{-1} \text{ is the reciprocal of the distribution function of } \gamma.
\]
When studying the isoperimetric or shift function of a product measure \( \mu \otimes \nu \), it will be useful to compare \( I_\mu \) or \( S_\mu \) with \( I_\gamma = S_\gamma \). It turns out that such comparisons are equivalent to Bobkov or reverse Bobkov-type inequalities (see [6, 9]):

**Theorem 1** [7]. Let \( M \) be a Riemannian manifold and \( \mu \) a probability measure on \( M \), admitting a density with respect to the Riemannian volume. Let \( c > 0 \). Then the following assertions are equivalent:

1. \( I_\mu \geq c I_\gamma \)
2. For all locally Lipschitz functions \( f: M \to [0, 1] \),
   \[
   I_\gamma \left( \int f \, d\mu \right) \leq \sqrt{I_\gamma^2(f) + \frac{1}{c^2} |\nabla f|^2} \, d\mu.
   \]

**Remark.** Actually, the paper [7] proves this equivalence for the standard Gaussian \( g(t) = \exp(-t^2/2)/\sqrt{2\pi} \), \( t \in \mathbb{R} \), not for \( \gamma \). The statement remains true for \( \gamma \) because \( I_\gamma = \sqrt{2\pi} I_{\gamma_{\mathbb{R}}} \).

Now, we extend to manifolds a result of [6]:

**Theorem 2.** Let \( \mu \) a probability measure on an embedded manifold \( M \subset \mathbb{R}^k \). Assume that \( \mu \) admits a density \( \rho_\mu \) with respect to the Riemannian volume on \( M \). Let \( c > 0 \). Then the following assertions are equivalent:

1. \( S_\mu \leq c I_\gamma \)
2. For all smooth and compactly supported functions \( f: M \to [0, 1] \),
   \[
   I_\gamma \left( \int f \, d\mu \right) \geq \sqrt{\left( \int I_\gamma(f) \, d\mu \right)^2 + \frac{1}{c^2} \int |\nabla f|^2} \, d\mu.
   \]

Here, \( \nabla f \) is considered as a vector of \( \mathbb{R}^k \) (tangent to \( M \)) and \( |\cdot| \) is the Euclidean norm on \( \mathbb{R}^k \).

**Proof.** We show first that (ii) implies (i). Notice that (ii) can be extended to continuous piecewise \( C^1 \) functions with compact support. Let \( A \) be a smooth compact domain in \( M \). For \( \varepsilon > 0 \), let \( f_\varepsilon: M \to [0, 1] \) be defined by

\[
f_\varepsilon(x) = \max \left( 0, 1 - \frac{1}{\varepsilon} d(x, A) \right),
\]
where $d$ is the geodesic distance. Applying (ii) to $f_\varepsilon$, one gets
\[
\left| \frac{1}{\varepsilon} \int_{A_\varepsilon - A} \nabla f(\cdot, A) \, d\mu \right| \leq c I_\varepsilon \left( \int f_\varepsilon \right).
\]
Notice that $\nabla d$ has norm one outside $A$. Close to the boundary of $A$, it becomes orthogonal to it. Thus, letting $\varepsilon$ to zero, we get $|\int_{\partial A} n_\mu \rho_\mu \, d\sigma_\mu| \leq c I_\mu(\mu(A))$.

Next, we assume (i) and show (ii). Let $f$ be smooth and compactly supported. Let $\mu$ be the distribution of $f$ under $\nu$. We may assume that $\nu$ is absolutely continuous with respect to the Lebesgue measure on $[0, 1]$ and has positive density on its support. By the co-area formula
\[
\int \nabla f \, d\mu = \int_0^1 \int_{\partial A_t} \nabla f \left| \rho_\mu \, d\sigma_t \right| \, dt,
\]
where $A_t = \{ x : f(x) \geq t \}$ and $\sigma_t$ is the surface measure on $\partial A_t$. Since $\nabla f / |\nabla f|$ is a unit inner normal of $A_t$, we get by (i)
\[
\int \nabla f \, d\mu \leq \int_0^1 \int_{\partial A_t} n_\mu \rho_\mu \, d\sigma_t \, dt \leq c \int_0^1 I_\mu(\mu(A_t)) \, dt.
\]
Let $N(t) = \mu(\{ f \leq t \}) = \nu(\{ 0, t \})$. Define $k = N^{-1} \circ R$, and apply the reverse Bobkov inequality of [1] to $k$ and the measure $\gamma_1$ (again, [1] deals with the standard Gaussian, but the inequality remains valid after scaling):
\[
I^2 \left( \int_{\mathcal{R}} k \, d\gamma_1 \right) \geq \int_{\mathcal{R}} k' \, d\gamma_1 \right)^2 + \left( \int_{\mathcal{R}} I_\gamma(k) \, d\gamma_1 \right)^2.
\]
By the change of variable $t = k(x)$,
\[
\int_{\mathcal{R}} k'(x) \, d\gamma_1(x) = \int_0^1 \rho_\gamma(k^{-1}(t)) \, dt = \int_0^1 I_\gamma(N(t)) \, dt.
\]
Since the law of $k$ under $\gamma_1$ is equal to the one of $f$ with respect to $\mu$, we get
\[
\left( \int I_\gamma(\mu(A_t)) \, dt \right)^2 = \left( \int I_\gamma(\mu(\{ f \leq t \})) \, dt \right)^2 \leq I^2 \left( \int f \, d\mu \right) - \left( \int I_\gamma(f) \, d\mu \right)^2,
\]
where we have used $I(p) = I(1 - p)$. Thus we get (ii) and the proof is complete.

As stated in [6, 7, 12] the functional inequalities in the latter two theorems have the tensorisation property: if they are true for $\mu$, then they
Corollary 3. Let \( \mu \) be a probability measure on \( M \) and let \( \mu^\otimes n \) be the product measure on \( M^n \).

(i) If \( I_\mu \geq c I_\nu \), then for \( n \geq 1 \) one has \( I_{\mu^\otimes n} \geq c I_\nu \).

Assume \( M \) is embedded.

(ii) If \( S_\mu \leq d I_\nu \), then for \( n \geq 1 \), \( S_{\mu^\otimes n} \leq d I_\nu \).

Let us emphasize that we consider on \( M^n \) the canonical Riemannian product structure. For the shift problem, if \( M \) is embedded in \( \mathbb{R}^k \), we consider the canonical product embedding of \( M \) in \( \mathbb{R}^{nk} \). Let us give a few comments:

(1) It is clear that \( I_\mu \geq I_{\mu^\otimes 2} \geq I_{\mu^\otimes 3} \ldots \) and \( S_\mu \leq S_{\mu^\otimes 2} \leq S_{\mu^\otimes 3} \ldots \). Moreover, if \( \mu \) is on \( \mathbb{R} \) and has finite variance, classical central limit arguments about the sets \( \{ x \in \mathbb{R}^n : \sum_{i=1}^n x_i \leq t \sqrt{n} \} \) show that \( \inf_{\mu} I_{\mu^\otimes n} \approx \mathcal{C} I_\nu \) and \( \sup_{\mu} S_{\mu^\otimes n} \approx C I_\nu \) for some constant \( C \) depending on the variance. Thus, in terms of behaviour close to zero, \( I_\nu \) is maximal for (i) and minimal for (ii).

(2) Similar results were established earlier. Let \( J(t) = \min(t, 1-t) \).

Bobkov and Houdré [12] showed that \( I_\mu \geq cJ \implies I_{\mu^\otimes n} \geq c(2 \sqrt{6}) J \) for all \( n \geq 1 \). In [10], Bobkov shows, for \( H(t) = t \log(1/t) + (1-t) \log(1/(1-t)) \), that \( S_\mu \leq cH \implies S_{\mu^\otimes n} \leq 24c H \) for \( n \geq 1 \).

(3) The remarkable fact about \( I_\nu \) is that there is no loss on the constant \( c \) when going to product measures. We shall show that \( I_\nu \) is almost the only one with this property. Let \( K : (0, 1) \to (0, \infty) \) be a positive, concave function such that for all \( t \), \( K(1-t) = K(t) \). Assume that for every probability measure \( \mu \) on \( \mathbb{R} \), \( I_\mu \geq K \) implies \( I_{\mu^\otimes n} \geq K \). By [8], there exists an even log-concave probability \( \nu \) on \( \mathbb{R} \) such that \( I_\nu = I_{\nu^\otimes 2} \). But \( K \leq I_\nu \), which is clearly less than \( I_\nu \). So \( I_\nu = I_{\nu^\otimes 2} = \nu \circ R_{\nu}^{-1} \), which means that half-spaces of the form \( \{ x_1 \leq x \} \) are solution to the isoperimetric problem. By [11], this implies that \( \nu \) is either a Gaussian (and \( I_\nu = I_{\nu} \)) or a Dirac mass at a point, which is excluded.

The situation is the same for the shift problem. Let \( K \) be concave positive and symmetric as before and such that \( S_\mu \leq K \) implies \( S_{\mu^\otimes n} \leq K \). Consider again the log-concave probability \( \nu \) on \( \mathbb{R} \) such that \( K = \nu \circ R_{\nu}^{-1} \). We show in the next section \( S_\nu = K \). Again we can deduce from this that \( S_{\nu^\otimes n} = \nu \circ R_{\nu}^{-1} \), which means that half-spaces \( \{ x_1 \leq x \} \) are solution to the shift problem. One can check that all the steps of the proof in [11] can be carried out in this new situation. This is due to the fact that their argument only

hold for \( \mu^\otimes n \) for all \( n \geq 1 \). This remark yields the following result, which is the basis of our comparison method.
uses half-spaces for which boundary measure and norm of the integral of
the outer normal coincide. The result is again that $K$ is a multiple of $I_I$.

Next, we take advantage of the previous property of $I_I$ to get exact solu-
tions of isoperimetric problems. The shift case is similar. Assume that $\mu$ is
such that $I_\mu \geq c I_I$ and that there exists $a \in (0, 1)$ such that $I_\mu(a) = c I_I(a)$
(i.e. $c$ is maximal so that $I_\mu \geq c I_I$). By the previous results and remarks, we
have

$$I_\mu(a) = c I_I(a) \leq I_\mu \otimes s(a) \leq I_\mu(a).$$

Thus $I_\mu \otimes s(a) = I_\mu(a)$. Let $A$ be a solution of measure $a$ of the isoperimetric
problem for $\mu$, $\mu(A) = a$, $\mu^+(A) = I_\mu(a)$. Then $A \times M^{n-1} \subset M^n$ satisfies
$\mu \otimes^n(A \times M^{n-1}) = \mu(A) = a$ and

$$(\mu \otimes^n)^+(A \times M^{n-1}) = \mu^+(A) = I_\mu(a) = I_\mu \otimes s(a).$$

So, for all $n$, $A \times M^{n-1}$ is a solution of the isoperimetric problem of
measure $a$.

In the next sections we give applications of this methods in concrete
cases. Each time, we try to have exact comparisons with the Gaussian case.

2.1. Products of Log-Concave Measures on the Real Line

The isoperimetric problem for log-concave measures on the real line was
solved by Bobkov [8]. In particular, he proves:

**Proposition 4.** Let $\mu$ be a log-concave probability measure on the real
line. Then, $\mu$ is symmetric around its median if and only if for all $0 < p < 1$
and all $h > 0$, the infimum of $\mu(A + [-h, h])$ over the sets $A$ such that
$\mu(A) = p$ is achieved for an interval of the form $(-\infty, a]$.

For convenience, we will always assume that $0$ is a median of our
measures. The previous result has the following infinitesimal corollary. Recall that $\rho_\mu$ is the density of $\mu$ and $R_\mu$ is its distribution function.

**Proposition 5.** Let $\mu$ be a log-concave even probability measure on $\mathbb{R}$,
then its isoperimetric function is given by $I_\mu(0) = I_\mu(1) = 0$ and for $t \in (0, 1)$,

$$I_\mu(t) = \rho_\mu(R_\mu^{-1}(t)).$$

We will need a similar statement for the shift problem. The results have the
same form.
Lemma 6. Let $\nu$ be a log-concave probability measure on the real line, with positive density $\rho_*=e^{-N}$. Let $0<p<1$ and $h>0$, then
\[
\sup\{\nu(A+h);\,\nu(A)=p\}
\]
is achieved for intervals of the form $(-\infty, a]$.

Proof. One can see from the formula
\[
\nu(A+h) = \int_A e^{-(N(x+h)-N(x))} \, d\nu(x)
\]
that, given $p$ and $h$, the supremum is achieved for $A_0 = \{x; N(x+h) - N(x) \leq \alpha\}$ where $\alpha$ is chosen so that $\nu(A_0) = p$. Since $N$ is convex, the function $x \to N(x+h) - N(x)$ is non-decreasing. Thus one can take $A_0 = (-\infty, R_{\nu^{-1}}(p))$.

Notice that $\inf\{\nu(A+h);\,\nu(A)=p\}$ is achieved on sets of the form $[b, \infty)$. And one has reversed results when $h$ is negative. Letting $h$ to zero, one easily gets

Proposition 7. Let $\nu$ be a log-concave even probability measure on $\mathbb{R}$ with positive density, then its shift function is given by $S_\nu(0) = S_\nu(1) = 0$ and for $0 < t < 1$,
\[
S_\nu(t) = \rho_*(R_{\nu^{-1}}(t)).
\]

We have computed isoperimetric and shift functions. The next statement is useful in comparing them.

Lemma 8. Let $\mu$ and $\nu$ be even log-concave probability measures on $\mathbb{R}$, with densities $\rho_\mu$ and $\rho_\nu$. Let $m \in [0, \infty]$ be the supremum of the support of $\mu$. Assume that $\rho_\nu$ is positive decreasing on $[0, \infty)$ and that $\rho_\nu(0) = 1$.

If $\rho_\nu^{-1} \circ \rho_\mu$ is convex on $[0, m]$, then for $0 < t < 1$, $\rho_\nu \circ R_\nu^{-1}(t) \geq \rho_\mu \circ R_\mu^{-1}(t)$.

Proof. Notice that $\rho_\nu^{-1} \circ \rho_\mu$ is well defined. By symmetry of the measures, we can restrict to $t \in [1/2, 1]$. The announced inequality is equivalent to $t \geq R_\nu \circ \rho_\nu^{-1} \circ \rho_\mu \circ R_\nu^{-1}(t)$, for $t \in [1/2, 1]$. Setting $t := R_\mu(y)$, we have to show that for $y \in [0, m]$,
\[
f(y) := R_\mu(y) - R_\mu((\rho_\nu^{-1} \circ \rho_\mu)(y))
\]
is non-negative. Obviously,
\[ f'(y) = \rho_\mu'(y)(1 - (\rho_\nu^{-1} \cdot \rho_\mu)'(y)), \]
where ' stands for right-derivative. By hypothesis, \((\rho_\nu^{-1} \cdot \rho_\mu)'\) is non-decreasing. Thus, \(f'\) can either be of constant sign on \([0, m]\) or be non-negative on some \([0, a)\) and then non-positive on \((a, m)\). But \(f\) is continuous and satisfies \(f(0) = 0\) and
\[ \lim_{m \to \infty} f = R_\mu(m) - \lim_{m \to \infty} R_\nu \cdot \rho_\nu^{-1} \cdot \rho_\mu = 1 - \lim_{m \to \infty} R_\nu \cdot \rho_\nu^{-1} \cdot \rho_\mu \geq 0. \]
So, in both cases, \(f\) has to be non-negative.

Combining this lemma with Corollary 3 and the preceding computations of isoperimetric and shift functions, we get

**Theorem 9.** Let \(\mu\) be an even absolutely continuous log-concave probability measure on \(\mathbb{R}\). We write \(d\mu = e^{-M} d\lambda\), where \(M: \mathbb{R} \to [0, \infty)\) is convex. Assume that \(M(0) = 0\).

(i) If \(\sqrt{M}\) is convex, then for every integer \(n\), one has \(I_{\mu^n} \geq I_\gamma\). In particular, among sets of measure \(1/2\) for \(\mu^n\), the half-space \([0, \infty) \times \mathbb{R}^{n-1}\) is solution to the isoperimetric problem.

(ii) If \(\sqrt{M}\) is concave, then for integer \(n\), \(S_{\mu^n} \leq S_\gamma\). In particular, among sets of measure \(1/2\) for \(\mu^n\), the half-space \([0, \infty) \times \mathbb{R}^{n-1}\) is solution to the shift problem.

**Proof.** We start with (i). The function \(\rho_\nu^{-1} \cdot \rho_\mu = \sqrt{M} / \pi\) is convex. Thus, we can apply the preceding lemma to \(\mu\) and \(v = \gamma\). By Proposition 5, the outcome of Lemma 8 reads as \(I_{\mu^n} \geq I_\gamma\), for \(t \in [0, 1]\). Notice that this inequality is an equality for \(t = 1/2\) (the set \([0, \infty)\) has \(\mu\)-boundary measure \(1 = I_\gamma(1/2)\).) By Corollary 3, we have \(I_{\mu^n} \geq I_\gamma\). The end of the proof follows the last paragraph of the introduction of Section 2: since \(I_\nu(1/2) = I_{\mu^n}(1/2) = I_\mu(1/2) = 1\), we know that \(I_{\mu^n}(1/2) = 1\). One easily checks that, for \(\mu^n\), \([0, \infty) \times \mathbb{R}^{n-1}\) has measure \(1/2\) and boundary measure 1. Thus, it is a solution of the isoperimetric problem for \(\mu^n\).

The proof of (ii) is similar. One applies Lemma 8 to \(\gamma\) and \(\mu\) (in this order). Notice that the hypothesis “\(M\) convex and \(\sqrt{M}\) concave” implies that the density \(\rho_\mu = e^{-M}\) is positive and decreasing on \(\mathbb{R}^+\). One gets \(\rho_\nu \cdot R_\nu^{-1} \geq \rho_\mu \cdot R_\mu^{-1}\). Using Proposition 5, one can rewrite this in terms of shift functions: \(S_\gamma \geq S_{\mu^n}\). Part (ii) of Corollary 3 gives the result.

This theorem can be applied to the probability measures \(d\mu_p = e^{-p|\nu|}\). They are in the case (i) when \(p \geq 2\) and in the case (ii) when \(1 \leq p \leq 2\).
Remark. If $v$ is the push forward of a measure $\mu$ by a Lipschitz map $f$, it is well known that $\|f\|_{\text{Lip}} I_\gamma \geq I_\nu$. In particular, if $\mu$ is a probability on $\mathbb{R}^n$,

$$\inf_{(0,1)} \frac{I_\nu}{I_\gamma} \geq \sup \{1/\|f\|_{\text{Lip}} : f(\gamma \otimes \nu) = \mu\}.$$ 

When $n = 1$, the latter is an equality [22]. The optimal map is then given by the canonical monotone transportation defined by $R_n = R_n \circ f$. Notice that $f$ is a contraction if and only if $\left| f \right| = \rho_n / (\rho_n \circ R_n^{-1} \circ R_n)$, and we recover the condition $\rho_n \circ R_n^{-1} \leq \rho_n \circ R_n^{-1}$. When this holds, the map $f_n(x_1, \ldots, x_n) = (f(x_1), \ldots, f(x_n))$ is a contraction of $\gamma \otimes \mu$ onto $\mu \otimes)^n$, thus $I_\gamma \leq I_\nu$. These classical arguments provide a slightly simpler proof of the statement (i) in the previous theorem. However, they do not work for the shift problem. In larger dimensions, building transportations is more difficult and, a priori, does not give the optimal constants in comparisons of isoperimetric functions.

### 2.2. Products of Spherical Measures

For $n \in \mathbb{N}$, let $S^n \subset \mathbb{R}^{n+1}$ be the Euclidean unit sphere and let $s_n$ denote its $n$-dimensional Lebesgue measure, by convention $s_0 = 2$. As already explained, we work on a sphere of suitable radius, so that the isoperimetric function takes value 1 at $1/2$. Let $r_n = s_{n-1}/s_n$. We consider $r_n S^n \subset \mathbb{R}^{n+1}$ with the Riemannian structure induced by $\mathbb{R}^{n+1}$. Let $\sigma_n$ be the uniform probability on this special sphere.

The measure of a spherical cap $C_t = \{ x \in r_n S^n : \langle x, e_1 \rangle \leq t \}$ is, for $|t| \leq r_n$

$$\Phi_n(t) := \sigma_n(C_t) = \int_{-r_n}^t \left(1 - \left(\frac{u}{r_n}\right)^2\right)^{(n-2)/2} du,$$

whereas the boundary measure of $C_t$ with respect to the normalized volume $\sigma_n$ is

$$\varphi_n(t) := \left(1 - \left(\frac{t}{r_n}\right)^2\right)^{(n-1)/2}.$$

Since spherical caps are solution to the isoperimetric problem [24, 29], the isoperimetric function of $\sigma_n$ is

$$I_{r_n S^n}(t) = \varphi_n(\Phi_n^{-1}(t)), \quad t \in [0,1].$$

It is obviously symmetric with respect to $1/2$ and decreasing on $[1/2;1]$.

Next, we compute the total normal $\int_{C_t} n_{C_t} \cdot d\tilde{C}_t$ for these caps, where $\tilde{C}_t$ is the surface measure on the boundary of $C_t$ induced by the normalized
volume \( \sigma_n \) on \( r_n S^n \). By rotational invariance, it is parallel to \( e_1 \). At any boundary point, one has \( \langle n_C, e_1 \rangle = -\sqrt{1 - (t/r_n)^2} \). Thus

\[
\varphi_n(t) := \left| \int_{\partial C} n_C \ d\mathcal{C}_t \right| = \sqrt{1 - \left( \frac{t}{r_n} \right)^2} \varphi_n(t) = \left( 1 - \left( \frac{t}{r_n} \right)^2 \right)^{n/2}.
\]

Our next result asserts that caps are also solution to the shift problem.

**Theorem 10.** The shift function of the sphere is

\[ S_{r_n S^n} = \varphi_n \circ \Phi_n^{-1}. \]

For \( n \geq 2 \), \( S_{r_n S^n} = (I_{r_n S^n})^{(n(n-1))} \).

**Proof.** Let \( a \in [0,1] \). We consider only smooth functions \( f: r_n S^n \rightarrow [0,1] \). By rotational invariance (of the norm and of the sphere),

\[
\sup \{ f = a \} \left| \int f d\sigma_n \right| = \sup \{ f = a \} \left| \langle \nabla f, -e_1 \rangle \right| d\sigma_n.
\]

By Green's formula

\[
\int \langle \nabla f, -e_1 \rangle \ d\sigma_n = n \int f(x) \left( -e_1, \frac{x}{r_n} \right) \ d\sigma_n(x).
\]

Under the condition \( \int f = a \), the latter integral is maximal when \( f \) is the characteristic function of the cap \( C_{\Phi_n^{-1}(a)} \). This implies that for smooth \( f \),

\[
\left| \int f d\sigma_n \right| \leq S_{r_n S^n} \left( \int f d\sigma_n \right).
\]

Applying this to approximations of characteristic functions of sets, as in section 2, we get the result for sets: when \( \sigma_n(A) = \sigma_n(C_t) \), one has \( \left| \int_{\partial A} n_A \ d\mathcal{C}_t \right| \leq \left| \int_{\partial C} n_C \ d\mathcal{C}_t \right| \).

**Proposition 11.** Let \( n \geq 1 \), then for \( t \in [0,1] \)

\[ S_{r_n S^n}(t) \leq S_{r_{n+1} S^{n+1}}(t) \leq I_{r_n S^n}(t) \leq I_{r_{n+1} S^{n+1}}(t) \leq S_{r_n S^n}(t), \]

with equality only at \( t = 0, 1/2, \) and 1.

When \( n = 2 \), we recover the inequalities \( 2\sqrt{1-t} \geq I_r \geq 4(1-t) \) which were noticed respectively in [21] and [6].

**Proof.** We show first the right hand side inequality. By symmetry, it is enough to prove it on \([1/2,1]\). Notice that, by construction, there is
equality at the end points of this interval. We want to show that for $x \in [1/2, 1]$,

$$
\left(1 - \left(\frac{\phi_{n+1}^{-1}(x)}{r_{n+1}}\right)^2\right)^{n/2} \leq \left(1 - \left(\frac{\phi_n^{-1}(x)}{r_n}\right)^2\right)^{(n-1)/2}.
$$

Since $\phi_{n+1}$ is increasing, this is equivalent to

$$
\phi_{n+1} \left(r_{n+1} \left[1 - \left(1 - \left(\frac{\phi_n^{-1}(x)}{r_n}\right)^2\right)^{(n-1)/2}\right]\right) \leq x,
$$

for $x \in [1/2, 1]$. Setting $x = \phi_n(r_n y)$, $y \in [0, 1]$, we have to check that for $y \in [0, 1]$, the following function is non-negative:

$$
f(y) = \phi_n(r_n y) - \phi_{n+1}(r_{n+1} \left[1 - (1 - y^2)^{(n-1)/2}\right]).
$$

For $y \in (0, 1)$, its derivative is

$$
f'(y) = r_n (1 - y^2)^{(n-2)/2} - r_{n+1} (1 - y^2)^{(n-2)/2} \frac{\partial}{\partial y} \left(1 - (1 - y^2)^{(n-1)/2}\right)$$

$$
= (1 - y^2)^{(n-2)/2}
\times \left[r_n - \frac{n-1}{n} r_{n+1} y (1 - y^2)^{1/2} (1 - (1 - y^2)^{(n-1)/2})^{-1/2}\right].
$$

So $f'(y) \geq 0$ is equivalent to

$$
\frac{(1 - y^2)^{1/n} - 1}{y^2} \geq \left(\frac{n-1}{nr_n}\right)^2 - 1.
$$

Since $t \rightarrow t^{1/n}$ is concave, the left quantity is decreasing on $(0, 1)$. So, either $f$ is monotone on $(0, 1)$, or there exists a such that $f$ increases on $(0, a)$ and decreases on $(a, 1)$. Recall that $f(0) = f(1) = 0$ (and $f$ is not constant). Thus the first possibility is excluded. It is then clear that $f$ is non-negative.

The inequality $I_n \leq I_{n+1}$ can be proved with the same method. It can be understood by the Poincaré limit argument: the sequence $(I_n)_{n \geq 1}$ is non-increasing, and $I_n$ is its limit. Indeed, for a fixed $x \in \mathbb{R}$, when $n$ tends to infinity,

$$
\psi_n(x) = \exp \left(\frac{n-2}{2} \ln \left(1 - \frac{x^2}{r_n}\right)\right) \sim e^{-\frac{(n-2)x^2}{2r_n}} \sim e^{-\pi x^2},
$$
and in the same way $\Phi_n(x) \to R_n(x)$. The inequalities involving the shift functions have a similar proof.

By the previous comparisons and by the results of Section 2, we have

**Theorem 12.** Let $f : (r_n S^n)^k \to [0, 1]$ be smooth. Then

$$I_{r_n} \left( \int f \, d\sigma_n^\otimes k \right) \leq \sqrt{I_{r_n}^2(f) + |\nabla f|^2} \, d\sigma_n^\otimes k,$$

and

$$I_{r_n} \left( \int f \, d\sigma_n^\otimes k \right) \geq \sqrt{\left( \int I_{r_n}(f) \, d\sigma_n^\otimes k \right)^2 + \left| \nabla f \, d\sigma_n^\otimes k \right|^2}.$$

In particular $I_{r_n S^n^k} \geq I_x \geq S_{r_n S^n^k}$.

The latter inequality appeared for $k = 1$, in a slightly different form, in [6].

**Corollary 13.** Let $S_n^k = \{ (x_i)^{n+1}_i \in S^n ; x_1 \geq 0 \}$. Among subsets of measure $1/2$ in a product of $k$ spheres of dimension $n$, the set $S_n^k \times (S^n)^{k-1}$ is solution to the isoperimetric and to the shift problem.

### 2.3. Products of Uniform Measures on Euclidean Balls

The isoperimetric problem for the uniform distribution on the Euclidean ball was solved by Burago and Maz'ja (see [25, p. 163]). The case of dimension 1 is simple. From now on we work in dimension $n \geq 2$. Solution sets are intersections with orthogonal balls or their complements. Let $v_n$ be the volume of the Euclidean unit ball $B_n^2$. Set $R_n = v_n^{-1}/v_n$. We will consider the uniform probability $\lambda_n$ on $R_n B_n^2$. Now we give a description for the solutions of measure larger than $1/2$. Let $m \geq R_n$ and $\rho \in [m - R_n, m]$. The ball $me_1 + \rho B_n^2$ crosses $B_n^2$. The intersection lies in the hyperplane $\{ x_1 = a \}$ where $a \geq 0$ satisfies $R_n^2 - a^2 = \rho^2 - (m - a)^2$. The boundaries of the two balls intersect orthogonally if $m^2 = R_n^2 + \rho^2$. In that case, $B_n^2 \setminus (me_1 + \rho B_n^2)$ is a solution to the isoperimetric problem, with measure larger than $1/2$, and all solutions for measure $\geq 1/2$ are isometric to such a set. The solution for volume $1/2$ is the half-ball; this corresponds to $m$ and $\rho$ infinite, when the other ball becomes a half-space.

These sets can be viewed as a one-parameter family indexed by $x := a/R_n \in [0, 1]$. One easily checks that it is an increasing function of $x$,
in the sense of the inclusion order. For a given \( \alpha \), we express \( \lambda_\alpha \)-measure and boundary measure. First the volume
\[
V(\alpha) = \int_{-R_n}^{R_n} v_{n-1}(R_n^2 - t^2)^{(n-1)/2} \frac{dt}{v_n R_n^2} - \int_{m-a}^{m+a} v_{n-1}(\rho^2 - s^2)^{(n-1)/2} \frac{ds}{v_n R_n^2}
\]

\[
= R_n \left[ \int_{-1}^{1} (1 - t^2)^{(n-1)/2} dt - \left( \frac{\sqrt{1 - \alpha^2}}{\alpha} \right)^n \int_{-1}^{1} (1 - \sigma^2)^{(n-1)/2} d\sigma \right],
\]

where we have used the relations \( m = R_n^2/a, \rho = R_n \sqrt{R_n^2 - a^2}/a \), the definition of \( R_n \) and the change of variables \( t = R_n \tau \) and \( s = \rho \sigma \). In the same way the boundary measure is
\[
S(\alpha) = \int_{m-a}^{m+a} s_{n-2}(\rho^2 - s^2)^{(n-1)/2} \frac{ds}{v_n R_n^2}
\]

\[
= (n-1) \left( \frac{\sqrt{1 - \alpha^2}}{\alpha} \right)^{n-1} \int_{-1}^{1} (1 - \sigma^2)^{(n-1)/2} d\sigma.
\]

Clearly, the right parameter is \( \theta \in (0, \pi/2) \) such that \( \alpha = \cos(\theta) \). Then
\[
v(\theta) := V(\cos \theta) = R_n \left[ \int_{\theta}^{\pi} \sin^* u \, du - \tan^* \theta \int_{\theta}^{\pi/2} \cos^* u \, du \right]
\]

\[
s(\theta) := S(\cos \theta) = (n-1) \tan^{n-1} \theta \int_{\theta}^{\pi/2} \cos^{n-2} u \, du.
\]

These functions can be extended by continuity: \( v(0) = 0, s(\pi/2) = 1 \), and \( v(\pi) = 1, v(\pi/2) = 1/2 \). On \([1/2, 1] \), the isoperimetric function of \( \hat{\lambda}_n \) is \( I_{R_n B_n} = S \cdot V^{-1} = s \cdot v^{-1} \). We have the following comparison with the Gaussian case

**Theorem 14.** Let \( n \geq 1 \), then for \( t \in [0, 1] \)
\[
I_{R_n B_n}(t) \geq I_{\lambda}(t),
\]

with equality only at \( t = 0, 1/2 \) and 1.

**Proof.** We start with some preliminary calculations. Notice that
\[
v'(\theta) = -n R_n \sin^{n-1} \theta \int_{\theta}^{\pi/2} \cos^n u \, du
\]

\[
s'(\theta) = (n-1) \frac{\sin^{n-2} \theta}{\cos^2 \theta} \left[ (n-1) \int_{\theta}^{\pi/2} \cos^{n-2} u \, du - \cos^{n-1} \theta \sin \theta \right].
\]
Writing \( \int_{\cos n u} \cos^n u du \) and integrating by parts in the latter integral shows that

\[
\int_{\cos^n u} \cos^n u du = (n - 1) \int_{\cos^n u} \cos^n u du - \cos^{n-1} u \sin \theta,
\]

thus \( x'(\theta)/x'(\theta) = -((n - 1)/R_x) \cdot (\cos \theta/\sin \theta) \). In particular \( s \) is increasing in \( \theta \) (we observed that \( x'(\theta) \) is negative for \( \theta \in (0, \pi/2) \)), and thus remains less than \( s(\pi/2) = 1 \). By symmetry, it is enough to show that \( x \cdot \cos^{-1} \leq x \cdot v^{-1} \) on \((1/2, 1) \). This is equivalent to the non-negativity on \((0, \pi/2) \) of the function

\[
f(\theta) = v(\theta) - R_y \left( -\frac{1}{\pi \ln s(\theta)} \right).
\]

Here we have used \( s \in [0, 1] \). Since \( f = 0 \) at the end points of this interval, we are done if we can prove that \( f' \) is first positive and then negative. After simplification one gets

\[
f'(\theta) = v'(\theta) + \frac{s'(\theta)}{2 \sqrt{-\pi \ln s(\theta)}}.
\]

Thus \( f'(\theta) \geq 0 \) is equivalent to

\[
g(\theta) := 4\pi \ln s(\theta) + \left( \frac{s'(\theta)}{v'(\theta)} \right)^2 \geq 0.
\]

Here one had to be careful about signs, which depend on the choice of parameters. When \( \theta \) tends to \( \pi/2 \), \( s(\theta) \) goes to 1 and \( \cos \theta \) to 0, thus \( \lim_{(\pi/2)^-} g = 0 \). When \( y \) goes to zero,

\[
\cos \theta \sim 1 / \sin \theta \quad \text{and} \quad s(\theta) \sim (n - 1) \theta^{n-1} \int_{0}^{\pi/2} \cos^{n-2} u du.
\]

So \( \lim_{y^+} g = +\infty \). It would be enough to show that \( g' \) is first negative and then positive. Clearly

\[
g'(\theta) = 4\pi \frac{s'(\theta)}{s(\theta)} - 2 \left( \frac{n-1}{R_y} \right)^2 \frac{\cos \theta}{\sin^3 \theta}.
\]
This quantity has the same sign as

\[
2\pi \sin^3 \theta s'(\theta) - \left(\frac{n-1}{R_n}\right)^2 \cos \theta s(\theta)
\]

\[
= 2\pi(n-1) \frac{\sin^{n+1} \theta}{\cos^n \theta} \left[(n-1) \int_\theta^{\pi/2} \cos^{n-2} u \, du - \cos^{n-1} \theta \sin \theta \right]
- \left(\frac{n-1}{R_n}\right)^2 \left(\cos \theta \tan^{n-1} \theta \right) \int_\theta^{\pi/2} \cos^{n-2} u \, du
\]

\[
= \left(2\pi(n-1) \frac{\sin^{n+1} \theta}{\cos^n \theta} - \left(\frac{n-1}{R_n}\right)^2 \sin^{n-1} \theta \right)
\times \left(\int_\theta^{\pi/2} \cos^{n-2} u \, du \right) - 2\pi \frac{\sin^{n+1} \theta}{\cos^n \theta} \times (n-1).
\]

Multiplying by \( \cos^n \theta/(n-1) \sin^{n-1} \theta \), we get that \( g' \) has the same sign as

\[
h_n(\theta) := \left(\int_\theta^{\pi/2} \cos^{n-2} u \, du \right) \left(2\pi(n-1) \sin^2 \theta - \left(\frac{n-1}{R_n}\right)^2 \cos^2 \theta \right)
- 2\pi \sin^3 \theta \cos^{n-1} \theta.
\]

Let \( \alpha_n = 2\pi(n-1), \beta_n = ((n-1)/R_n)^2 \) and \( \theta_n = \arctan(\sqrt{\beta_n/\alpha_n}) \). If \( \theta \in [0, \theta_n] \) then \( h_n(\theta) < 0 \). On \( (\theta_n, \pi/2) \), \( h_n(\theta) \) has the sign of

\[
j_n(\theta) = \left(\int_\theta^{\pi/2} \cos^{n-2} u \, du \right) \frac{2\pi \sin^3 \theta \cos^{n-1} \theta}{\alpha_n \sin^2 \theta - \beta_n \cos^2 \theta}.
\]

Notice that \( \lim_{\theta \to \theta_n} j_n = -\infty \) and \( j_n(\pi/2) = 0 \). We are done if we can prove that on \( (\theta_n, \pi/2) \), \( j_n \) is first negative and then positive. A straightforward computation yields

\[
j_n'(\theta) = \frac{\cos^{n-2} \theta}{(\alpha_n \sin^2 \theta - \beta_n \cos^2 \theta)^2} P_n(\sin^2 \theta),
\]

where \( P_n \) is a polynomial of degree 3, with leading term \( (\alpha_n + \beta_n) \cdot (\alpha_n + 2\pi) > 0 \). Moreover, \( P_n \) satisfies

\[
P_n \left(\frac{\beta_n}{\alpha_n + \beta_n}\right) > 0 \quad \text{and} \quad P_n(1) = 0.
\]
To study the variations of $j_n$, we just need to study $P_n$ on $[x_n, 1]$, where we have set $x_n = \frac{\beta_n}{\pi \alpha_n + \beta_n}$. Because of its degree, $P_n$ can decrease only on a bounded interval. Since $P_n(x_n) > P_n(1)$, this interval has to intersect the interval we are working on. If we can prove that $P_n'(1)$ is positive, then clearly $P_n$ is positive on $(x_n, \eta_n)$, and negative on $(\eta_n, 1)$ for some $\eta_n$ between $x_n$ and 1. In this case, $h_n$ is first negative and then positive and the theorem is proved. One easily checks that

$$P_n'(1) = \frac{\pi^2 + 2\pi x_n - 4\pi \beta_n}{R_n^2} - \frac{2 \pi (n-1)}{R_n^2} (2 \pi R_n^2 - n^2 + 1).$$

Recall that $R_n = \frac{v_n - 1}{v_n}$ with $v_n = \frac{\pi n}{1 + \frac{n}{2}}$. So $P_n'(1) > 0$ is equivalent to

$$1 + 2n \left( \frac{\Gamma(1+n/2)}{\Gamma(1+(n-1)/2)} \right)^2 > n^2.$$

But this follows from the next lemma.

**Lemma 15.** For all $t > 0$, one has

$$\frac{\Gamma(t+1)}{\Gamma(t+1/2)} \geq \sqrt{t}.$$

**Proof.** As the referee pointed out to us, this fact is an easy consequence of the Cauchy–Schwarz inequality:

$$\sqrt{t} \Gamma\left(t + \frac{1}{2}\right) = \int_0^\infty (\sqrt{t} x^{1/2} - 1/2) x^{1/2} e^{-x} dx$$

$$\leq (t \Gamma(t))^{1/2} (t \Gamma(t+1))^{1/2} = t + 1.$$  

From Theorems 1 and 14, we derive Bobkov's inequality with optimal constant on $R_n B_n^2$. Let $f: R_n B_n^2 \to [0, 1]$ be smooth. Then

$$I_f \left( \int_{R_n B_n^2} f d\nu_n \right) \leq \int_{R_n B_n^2} \sqrt{I_f^2(f) + |\nabla f|^2} d\nu_n. \quad (1)$$

As explained before, this yields an exact solution to the isoperimetric problem in $(B_n^2)^k$ for sets containing half of the whole volume. Let
$B_n^2 = \{(x_1, \ldots, x_n) \in B_n^2 : x_i \geq 0\}$, and $\mu_n$ be the uniform probability on $B_n^2$.

Among sets of probability $1/2$ in $(B_n^2)^k$, the set $B_n^2 \times (B_n^2)^{k-1}$ has minimal boundary measure.

For a probability $\mu$ on $\mathbb{R}^n$ and $f: \mathbb{R}^n \to [0, +\infty)$, denote

$$\text{Ent}_\mu(f) = \int f \log f \, d\mu - \left( \int f \, d\mu \right) \log \left( \int f \, d\mu \right).$$

By [1] or by Beckner’s limit argument (see [23]), inequality (1) implies a log-Sobolev inequality for $R_n B_n^2$. Let us state it for the unit ball $B_n^2$. Easy scaling arguments give that for every smooth $f: B_n^2 \to [0, +\infty)$,

$$\text{Ent}_\mu(f^2) \leq \left( \frac{(n+1)/2)}{(n+2)/2)} \right)^2 \int_{B_n^2} \|f\|^2 \, d\mu_n \leq \frac{2}{n} \int_{B_n^2} \|f\|^2 \, d\mu_n.$$

Here, we improve a result of Bobkov and Ledoux [13]: using a rotation-symmetric transportation of the Gaussian measure onto $\mu_n$, they got the constant $\Gamma(1+n/2)^{-2n} \sim \frac{2}{n} \frac{2e}{n}$. Our constant is asymptotically sharp when $n$ goes to infinity (notice that the previous inequality implies the sharp log-Sobolev inequality for the Gaussian measure, due to Gross [17]).

3. UNIMODALITY AND SECTIONS OF PRODUCT MEASURES

In [31], Vaaler proved that the volume of the sections of the cube $[-1/2, 1/2]^n$ by $k$-dimensional subspaces through the origin is always bigger than 1. Peaked order and unimodal measures [19] were the main ingredients of his proof. His method was pushed forward by several authors: Meyer and Pajor [26] proved that for any $k$-dimensional subspace $K \subset \mathbb{R}^n$, the function

$$s_K(p) := \frac{|K \cap B_p^n|}{|B_p^n|}$$

is non-decreasing for $p \geq 1$. They actually derived a more general statement for $\ell_p$-sums of Euclidean spaces. Next Caetano [16] established $s_K(p) \leq s_K(1)$ for $p \in (0, 1)$. In [3], we showed that $s_K$ is non-decreasing on $(0, +\infty)$. Our aim here is to extend these results to $\ell_p$-sums of arbitrary finite dimensional spaces and to apply the peaked order method to the study of the isoperimetric and the shift problem in the case of half-spaces. This partial approach nevertheless enables to deal with non log-concave product measures.
3.1. Some Preliminaries

Our definitions slightly differ from [19]. They lead to less technical proofs; for details we refer to [3].

Let $\mathcal{C}_n$ be the set of all bounded origin-symmetric convex Borel subsets of $\mathbb{R}^n$. A function $f$ on $\mathbb{R}^n$ is said to be unimodal if it is the increasing limit of a sequence of functions of the form,

$$
\sum_{j=1}^{J} a_j 1_{C_j},
$$

where $J \in \mathbb{N}$, $a_j \geq 0$, and $C_j \in \mathcal{C}_n$. One easily checks that even non-negative quasi-concave functions, and a fortiori even log-concave functions are unimodal. On the real line, a function is unimodal if and only if it is even and non-increasing on $\mathbb{R}_+$.

One says that a Radon measure on $\mathbb{R}^n$ is unimodal if it is absolutely continuous with respect to Lebesgue’s measure and admits a unimodal density. When $\mu$ and $\nu$ are unimodal measures, so is the product measure $\mu \otimes \nu$; this is due to the fact that when $C \in \mathcal{C}_n$ and $D \in \mathcal{C}_m$, one has $C \times D \in \mathcal{C}_{n+m}$ and $1_C(x)1_D(y) = 1_{C \times D}(x, y)$.

Let $\mu, \nu$ be Radon measures on $\mathbb{R}^n$. One says that $\mu$ is more peaked than $\nu$ and writes $\mu \succ \nu$ when $\mu(C) \geq \nu(C)$ holds for every $C \in \mathcal{C}_n$. It is remarkable that the inequalities for $\succ$ can be tensorised as soon as they involve unimodal measures:

**Theorem 16 [Kanter]** For $1 \leq i \leq k$, let $\mu_i$ and $\nu_i$ be unimodal measures on $\mathbb{R}^n$ such that $\mu_i \succ \nu_i$. Then, the following inequality between measures on $\mathbb{R}^{n_1 + \cdots + n_k}$ holds:

$$
\mu_1 \otimes \cdots \otimes \mu_k \succ \nu_1 \otimes \cdots \otimes \nu_k.
$$

**Proof (sketch).** The theorem reduces to the following: let $\mu, \nu$ be measures on $\mathbb{R}^n$ such that $\mu \succ \nu$ and let $\lambda$ be a unimodal measure on $\mathbb{R}^m$, then $\mu \otimes \lambda \succ \nu \otimes \lambda$. One easily checks that it is enough to consider the special case when $d\lambda(y) = 1_C(y) \, d^m y$, where $C \in \mathcal{C}_m$. Let $K \in \mathcal{C}_{m+n}$, then $\mu \otimes \lambda(K) = \int s(x) \, d\mu(x)$ where, for $x \in \mathbb{R}^n$,

$$
s(x) = \int_{\mathbb{R}^m} 1_{K \cap (\mathbb{R}^n \times C)}(x, y) \, d^m y
$$

is a section function of the symmetric and convex set $K \cap (\mathbb{R}^n \times C)$. Clearly, $s$ is even, and by the Brunn–Minkowski theorem (see, e.g., [28]) it is log-concave. Thus $s$ is unimodal. The peaked order inequality $\mu \succ \nu$ then implies $\int s \, d\mu \geq \int s \, d\nu$, that is, $\mu \otimes \lambda(K) \geq \nu \otimes \lambda(K)$. \[\square\]
3.2. Sections of Product Measures and of Unit Balls

**Lemma 17.** Let \( \phi_1, \phi_2, f \) be continuous functions from \( \mathbb{R}^+ \) to \( \mathbb{R}^+ \). Assume that \( f \) vanishes at most at zero and that \( \phi_1/\phi_2 \) is non-decreasing. If

\[
\int_0^\infty f e^{-\phi_1} \geq \int_0^\infty f e^{-\phi_2},
\]

then for all \( a \geq 0 \)

\[
\int_0^a f e^{-\phi_1} \geq \int_0^a f e^{-\phi_2}.
\]

This is obvious, studying variations in \( a \) of the latter two integrals. Notice that the statement can be extended to the case when \( \phi_1 \) and \( \phi_2 \) have values in \([0, \infty] \).

**Proposition 18.** Let \( \phi : \mathbb{R}^+ \rightarrow [0, \infty] \), be non-decreasing. Assume that \( \phi(0) = 0 \) and \( \int \exp[-\phi(|t|)] \, dt = 1 \). Let \( E \subset \mathbb{R}^n \) be a \( k \)-dimensional subspace.

(i) If \( \phi(t)/t^2 \) is non-increasing, then

\[
\int \prod_{i=1}^n e^{-\phi(|x_i|)} d^k(x) \leq \int \prod_{i=1}^n e^{-\phi(|x_i|)} d^k(x) = 1.
\]

(ii) If \( \phi(t)/t^2 \) is non-decreasing, then

\[
\int \prod_{i=1}^n e^{-\phi(|x_i|)} d^k(x) \geq \int \prod_{i=1}^n e^{-\phi(|x_i|)} d^k(x) = 1.
\]

**Proof.** Assume the hypothesis of (i). Lemma 17 implies that

\[
d\nu(t) := \exp[-\phi(|t|)] \, dt \ll \exp[-\pi t^2] \, dt.
\]

By Theorem 16, the inequality holds for the \( n \)th powers of these unimodal measures. Let \( (u_{k+1}, \ldots, u_n) \) be an orthonormal basis of \( E^\perp \). For \( \varepsilon > 0 \), let

\[
E(\varepsilon) = \{ x \in \mathbb{R}^n ; |\langle x, u_i \rangle| \leq \varepsilon/2, i = k+1, \ldots, n \}.
\]

Then \( \gamma^{\otimes n}(E(\varepsilon)) \leq \gamma^{\otimes n}(E(\varepsilon)) = \gamma^{\otimes n}(\mathbb{R}^k \times [-\varepsilon/2, \varepsilon/2]^{n-k}) \), where we have used the definition of the peaked order for the sets \( E(\varepsilon) \cap rB_2^n, r \to \infty \) and the rotational invariance of Gaussian measures. The conclusion follows from a standard limit argument. The proof of (ii) is similar. $\blacksquare$
Let $C \subset \mathbb{R}^n$ be a symmetric convex body and let $\|\cdot\|_C$ be the corresponding norm on $\mathbb{R}^n$. For $p > 0$, we set

$$\pi_{p,C} = \left( |C| \cdot \Gamma \left( 1 + \frac{n}{p} \right) \right)^{1/n}.$$

Notice that $n$ only depends on $C$. When $C = [-1, 1] \subset \mathbb{R}$, we simply write $\pi_p$. We are ready to state our extension of the results of Meyer and Pajor and Caetano.

**Theorem 19.** Let $N, m, (n_i)_{i=1}^m$ be positive integers such that $\sum_{i=1}^m n_i = N$. For $i \leq m$, let $C_i$ be a symmetric convex body in $\mathbb{R}^{n_i}$. Identifying $\mathbb{R}^N$ with $\mathbb{R}^{n_1} \times \cdots \times \mathbb{R}^{n_m}$, we write every $x \in \mathbb{R}^N$ as $x = (x_1, \ldots, x_m)$.

For $0 < p \leq \infty$, let us consider the sets

$$\mathcal{B}_p = \left\{ x \in \mathbb{R}^N : \sum_{i=1}^m \|x_i\|_{C_i}^p \leq 1 \right\} \quad \text{and} \quad \mathcal{D}_p = \left\{ x \in \mathbb{R}^N : \sum_{i=1}^m \|x_i\|_{C_i}^p \leq 1 \right\}.$$

Let $E$ be a $k$-dimensional subspace of $\mathbb{R}^N$. Then the quantity

$$\Pi(1 + k/p) \cdot |E \cap \mathcal{B}_p|$$

is a non-decreasing function of $p \in (0, +\infty]$. Under the additional condition $n_1 = \cdots = n_m = n$,

$$\left( \frac{|E \cap \mathcal{D}_p|}{|B^k_{p}|} \right)^{1/k} |B^k_{p}|^{1/n}$$

is a non-decreasing function of $p \in (0, +\infty]$.

An application of this result appears in [27]. See also [26] for applications to Siegel-type lemmas. We start with some preliminary statements.

Following Meyer and Pajor, we define the measure $\mu_{p,C}$ on $\mathbb{R}^n$ by

$$d\mu_{p,C}(x) = \exp(- \langle \pi_{p,C} x \rangle_C^p) \, d^n x.$$

It is a probability measure. Since the level sets of its density are convex and symmetric, it is unimodal.

**Proposition 20.** Let $C$ be a symmetric convex body in $\mathbb{R}^n$. If $p > q > 0$ then $\mu_{p,C} > \mu_{q,C}$. 

Proof. If \( n=1 \), the statement follows from Lemma 17 applied to \( f=1 \), \( \psi_1(t) = (\sigma_{p_t})^p \), \( \psi_2(t) = (\sigma_{q_t})^q \). Assume now \( n \geq 2 \). It is enough to consider sets \( C \) with \( C^\infty \) norm on \( \mathbb{R}^n \setminus \{0\} \). In this case the boundary \( \partial C \) of \( C \) is a submanifold. For \( \omega \in \partial C \), let \( n(\omega) \) be the outer normal of \( C \) at \( \omega \) and let \( d\sigma \) be the surface measure on \( \partial C \). We will use the diffeomorphism \( \Theta \) from \( \mathbb{R}^n \times \mathbb{R}^+ \) onto \( \mathbb{R}^n \setminus \{0\} \) which maps \((r, \omega)\) to the vector \( r\omega \).

Since we work with absolutely continuous measures, it is enough to compare their values on symmetric convex bodies. Let \( K \subset \mathbb{R}^n \) be such a set. One has

\[
\mu_\rho(K) = \int_{\mathbb{R}^n} 1_{\{|x| \leq 1\}} e^{-|x|^p c^k} \, dx \\
= \int_{\mathbb{R}^n \times \mathbb{R}^+} 1_{\{|x| \leq 1\}} e^{-|x|^p c^k} \langle \omega, n(\omega) \rangle r^{n-1} \, d\sigma(\omega) \\
= \int_{\mathbb{R}^n} \langle \omega, n(\omega) \rangle \left( \int_{r=0}^{1/|\omega|} e^{-q^k c^k r^{n-1}} \, dr \right) d\sigma(\omega).
\]

Taking \( K = \mathbb{R}^n \) in this formula shows that

\[
\int_0^\infty e^{-q^k c^k r^{n-1}} \, dr
\]

does not depend on \( p \). For each \( \omega \), we apply Lemma 17 with \( f(r) = r^{n-1} \), \( \phi_1(r) = (\sigma_{p_t} c r)^p \) and \( \phi_2(r) = (\sigma_{q_t} c r)^q \); the hypothesis \( p > q \) ensures that \( \phi_1/\phi_2 \) is non-decreasing. Since \( \langle \omega, n(\omega) \rangle \) is always non-negative, one gets \( \mu_\rho(K) \geq \mu_\rho(K) \).

Lemma 21. Given \( E \) a subspace of \( \mathbb{R}^n \) of dimension \( k \) and \((u_{k+1}, \ldots, u_n)\) an orthonormal basis of \( E^\perp \), we consider

\[ E(\varepsilon) = \{ x \in \mathbb{R}^n ; |\langle x, u_i \rangle| \leq \varepsilon/2, i = k+1, \ldots, n \}. \]

Let \( N: \mathbb{R}^n \to \mathbb{R}^+ \) be a continuous homogeneous function, vanishing only at the origin. Then the set \( B = \{ x ; N(x) \leq 1 \} \) is a symmetric star-shaped body and for \( p > 0 \), one has

\[
P \left( 1 + \frac{k}{p} \right) |E \cap B|_p = \int_{E} e^{-N(x)p} \, dx = \lim_{\varepsilon \to 0^+} \int_{E(\varepsilon)} e^{-N(x)p} \, dx.
\]

The first equality is obvious by level-sets integration. The second one follows from dominated convergence (notice that there exists \( d > 0 \) such that \( d|x| \leq N(x) \leq |x|/d \) for all \( x \in \mathbb{R}^n \)).
Proof of Theorem 19. Let \( p > q > 0 \). By Lemma 21 and with the same notation, the following relation holds for \( r > 0 \),
\[
\Gamma(1 + k/r) \cdot |E \cap \mathcal{B}_r| = \lim_{\eta \to 0} \eta^{k-N} \mu_r, c_1 \otimes \cdots \otimes \mu_r, c_n(E(\eta)).
\]
The previous proposition and Theorem 16 yield
\[
\mu_p, c_1 \otimes \cdots \otimes \mu_p, c_n \geq \mu_q, c_1 \otimes \cdots \otimes \mu_q, c_n.
\]
Since \( E(\eta) \) is convex and symmetric, the latter relation implies that
\[
\Gamma(1 + k/p) \cdot |E \cap \mathcal{B}_p| \geq \Gamma(1 + k/q) \cdot |E \cap \mathcal{B}_q|.
\]
When \( n_1 = \cdots = n_m = n \),
\[
\mathcal{B}_p = \left\{ x \in \mathbb{R}^N; \sum_{i=1}^m \left( \Gamma(1 + \frac{n}{p}) \frac{1}{n} |C_i|^{1/n} x_i \right)^p \leq 1 \right\}
\]
\[
= \Gamma(1 + \frac{n}{p})^{-1/n} \left\{ x \in \mathbb{R}^N; \sum_{i=1}^m \| |C_i|^{1/n} x_i \|_{C_i}^p \leq 1 \right\}
\]
The linear mapping \( T \) defined on \( \mathbb{R}^N \) by \( T(x) = (|C_1|^{1/n} x_1, ..., |C_m|^{1/n} x_m) \) is bijective. Thus
\[
\mathcal{B}_p \cap E = \Gamma(1 + \frac{n}{p})^{-1/n} T^{-1}(\mathcal{D}_p \cap TE)
\]
Notice that \( T \) multiplies volumes by \(|\det(T)|\) and that \( TE \) can be an arbitrary \( k \)-subspace. Hence for any \( F \) of dimension \( k \)
\[
p \to \frac{\Gamma(1 + k/p)}{\Gamma(1 + n/p)^k} |F \cap \mathcal{D}_p|
\]
is non-decreasing on \((0, +\infty)\). □

3.3. Remarks on the Brascamp–Lieb Inequalities

We are going to expose an alternative proof of the first statement in Proposition 18. It uses an inequality due to Brascamp and Lieb [15] (see also [2, 5]). Let \( E \) be a \( k \)-dimensional subspace of \( \mathbb{R}^n \) and let \( P \) be the orthogonal projection onto \( E \). Then \( \sum_{i=1}^n P_{e_i} \otimes P_{e_i} = P \) is the identity when restricted to \( E \). Set \( c_i = |P_{e_i}|^2 \) and \( u_i = P_{e_i}/|P_{e_i}| \). As linear mappings of \( E \), \( \sum_{i=1}^n c_i u_i \otimes u_i = \text{Id}_E \). The Brascamp–Lieb inequality yields
\[
\left( \prod_{i=1}^n e^{-\psi(\langle x, e_i \rangle)} \right) dx = \left( \prod_{i=1}^n \left( e^{-\psi(\sqrt{\gamma(\langle x, e_i \rangle/c_i)})} \right) dx \right) \cdot \left( \prod_{i=1}^n \left( e^{-\psi(\sqrt{\gamma(t)/c_i}) dt} \right) \right).
\]
Assume that \( \psi \) is even and \( \psi(t)/t^2 \) is non-increasing on \( \mathbb{R}_+ \). Since \( c_i \in (0, 1] \), one has \( \psi(\sqrt{c_i} t)/c_i \geq \psi(t) \) for all \( t \). Hence the previous integral is smaller than
\[
\left( \int_{\mathbb{R}} e^{-\psi(t)} dt \right)^{ \sum_{i=1}^{k} c_i } = \prod_{i=1}^{k} \int_{\mathbb{R}} e^{-\psi(t)} dx,
\]
where we have used \( \sum c_i = k \). Thus among \( k \)-dimensional subspaces, the canonical subspaces are extremal.

If one takes \( \psi(t) = |x_t|^p \), one can use homogeneity to improve on the latter argument and extend one of Ball’s volume estimates on sections of the unit cube \([2]\):
\[
\int_{E} e^{-|x|^p} dx \leq \prod_{i=1}^{n} \left( \int_{\mathbb{R}} e^{-|e_i|^{p(2-1/p)} dt} \right)^{1/p - 1/2}
\]
Since \( c_i \in (0, 1] \) and \( \sum_{i=1}^{n} c_i = k \), one has \( (k/n)^k \leq \prod c_i^i \leq 1 \). If \( p \leq 2 \), the integral is bounded by one as before. If \( p \geq 2 \), Lemma 21 and the previous estimate give
\[
\frac{|B_p^n \cap E|}{|B_p^n|} \leq \left( \frac{n}{k} \right)^{k(1/2 - 1/p)}.
\]
One can check that this is optimal when \( k \) divides \( n \). In this case, let \( d = n/k \) and for \( j = 1, \ldots, k \), let \( c_j = e_1^{(j-1)d-1} + \cdots + e_d^{(j-1)d-1} \). Then span\( \{e_1, \ldots, e_k\} \cap B_p^n \) is isometric to \((n/k)^{1/2 - 1/p} B_p^d\).

The second statement in Proposition 18 is a reverse form of the first statement. One can wonder whether it is provable via the reverse form of the Brascamp–Lieb inequality \([4, 5]\). The answer seems to be negative: the duality between the Brascamp–Lieb inequality and its converse corresponds to duality of convex sets. It turns sections into projections. Since projections are larger than sections, this provides weaker results. Let us give an example with \( \psi(t) = \exp(-|x_t|^p) \); By Lemma 21, and the reverse Brascamp–Lieb inequality, one can estimate from below the volume of the orthogonal projection of \( B_p^n \) onto a \( k \)-dimensional subspace \( E \). With the previous notation
\[
\frac{|P_E(B_p^n)|}{|B_p^n|} = \int_{E} e^{-\psi(\sum_{i=1}^{n} |x_i|^p, x = P(\sum_{i=1}^{n} e_i^j))} dx
\]
\[
= \int_{E} \sup_{\sum_{i=1}^{n} c_i^j u_i = x} \prod_{i=1}^{n} \left( e^{-|e_i|^{p(2-1/p)} |u_i|^2} \right)^{c_i^j} dx
\]
\[
\geq \prod_{i=1}^{n} \left( \int_{\mathbb{R}} e^{-|x|^{p(2-1/p)} |u_i|^2} dx \right)^{c_i^j} \left( \prod_{i=1}^{n} c_i^j \right)^{1/p - 1/2}.
\]
If $p \geq 2$, this is bigger than 1. This result was implied by the one on sections, because $E \cap B^n_p \in P_E(B^n_p)$. If $0 < p \leq 2$, we get

$$\frac{|P_E(B^n_p)|}{|B^n_p|} \geq \left( \frac{k}{n} \right)^{k(1/p - 1/2)}.$$

By duality, this is optimal when $k$ divides $n$ and $p \geq 1$. The equality is achieved for the same subspace as for sections.

ACKNOWLEDGMENTS

We thank S. Bobkov, M. Ledoux, M. Meyer, A. Pajor and the referee for useful comments. We gratefully acknowledge the hospitality of the Erwin Schrödinger International Institute for Mathematical Physics, in Vienna, and the department of Physics of Princeton University, where part of this research was carried out.
