A GENERALIZATION OF THE DIFFERENTIAL APPROACH TO RECURSIVE QUERY EVALUATION

I. BALBIN AND K. RAMAMOHANARAO

The differential (or seminaive) approach to query evaluation in function free, recursively defined, Horn clauses was recently proposed as an improvement to the naive bottom-up evaluation strategy. In this paper, we extend the approach to efficiently accommodate \( n \) recursively defined predicates in the body of a Horn clause.

1. INTRODUCTION

The differential (or seminaive) approach to query evaluation is described in [2], [3], [5]. Focusing on the naive bottom-up method of evaluation, the approach eliminates some of the obviously redundant joins. However, "the problem is not solved in its entirety and only a number of transformations are known" [4]. In this paper, we extend the differential approach to include nonlinear rules with \( n \) recursively defined predicates in the body.

2. PRELIMINARIES

2.1. A Naive Execution Model

The idea of translating a recursive clause or view into an iterative equivalent is not new (see [6], for example). Termination is assured due to the finiteness of the database, and when the clauses are defined using only positive literals, their monotonicity ensures the computation of the least fixed point [1].

For the case of nonhierarchical databases, the problem of looping becomes an issue. The solution proposed in [7], with respect to their active connection graphs.

amounts to checking whether all tuples generated at each iteration of the loop are
new. If this is not the case, the process is halted. For example, consider the iterative
program corresponding to the following database which computes the transitive
closure of $p$:

Example 1 (Transitive closure of $p$).

$s(X, Y) \leftarrow p(X, Y)$
$s(X, Y) \leftarrow p(X, Z) \land s(Z, Y)$

It can be viewed as computing

- $s_1(X, Y) = p(X, Y)$,
- $s_2(X, Y) = s_1(X, Y) + \Delta s_1(X, Y)$,
- $s_{j+1}(X, Y) = s_j(X, Y) + \Delta s_j(X, Y)$ for $j > 0$,
- $\Delta s_j(X, Y) = p(X, Z) \Join s_j(Z, Y)$,

where $p(X, Y)$ is a shorthand for $\{(X, Y) | p(X, Y) \text{ is proved}\}$, and, for any
predicate $s(X, Y)$, $s_j(X, Y)$ is defined as the set of $s$ tuples which have been proved
at the completion of the $j$th iteration; $\Join$ is the usual join operator, and $+$ is the set
union. $\Delta s_j$ is then the set of (possibly) new $s$ tuples which have been formed by
evaluating the join between $p$ and $s_j$.

This type of program, whilst attractive in the sense that it does not go into an
infinite loop, is fraught with some serious inefficiencies which are addressed by the
differential approach.

3. THE DIFFERENTIAL APPROACH

3.1. Linear Horn Clauses

Using the method of [5], [3], at iteration $j$, rather than evaluating $\Delta s_j$ by forming
the join between $p(X, Z)$ and $s_j(Z, Y)$, we compute

- $\Delta s_j(X, Y) = p(X, Z) \Join \delta s_{j-1}(Z, Y)$

where

- $\delta s_{j-1}(X, Y) = \Delta s_{j-1}(X, Y) - s_{j-1}(X, Y)$

and, $-$ denotes set difference. Thus, $\delta$ depicts the new tuples generated at that
iteration.

3.2. Extension to Nonlinear Horn Clauses

Ignoring variables, consider a recursive rule

$s \leftarrow c \land a \land w$

where

$c \leftarrow c^1 \land c^2 \land \cdots \land c^m$
and the $c^k$, $k = 1, \ldots, m$, are nonrecursively defined predicates; and $a$ and $w$ are recursively defined.

We write $ca_jw_j$ to represent the set of all ground instances for which $c \land a \land w$ is true at the $j$th iteration, that is, $c \land a_j \land w_j$.

Now, for $j \geq 0$

$$s_{j+1} = s_j + \delta s_j,$$

where

$$\delta s_j = ca_jw_j - s_j.$$

Replacing $a_j$ by its equivalent differential definition

$$a_j = a_{j-1} + \delta a_{j-1},$$

we obtain

$$\delta s_j = [c(a_{j-1} + \delta a_{j-1})w_j] - s_j.$$

Since $\land$ distributes over $+$, this simplifies to

$$\delta s_j = (ca_{j-1}w_j + ca_jw_j) - s_j.$$

Similarly, by replacing the second occurrence of $w_j$ with its equivalent differential definition

$$w_j = w_{j-1} + \delta w_{j-1},$$

we have

$$\delta s_j = [ca_{j-1}w_{j-1} + c(a_{j-1} + \delta a_{j-1})w_{j-1}] - s_j.$$

Since $ca_{j-1}w_{j-1} \subseteq s_j$, then

$$\delta s_j = (ca_{j-1}w_{j-1} + ca_{j-1}\delta w_{j-1}) - s_j.$$  \hspace{1cm} (I)

Equivalently, we can also derive

$$\delta s_j = (ca_{j-1}w_{j-1} + c\delta w_{j-1}a_j + \delta a_{j-1}) - s_j.$$  \hspace{1cm} (II)

In general, when the rule contains $\geq 1$ recursive predicates in the conjunction, the following theorem generalizes Equations (I) and (II) above.

**Theorem.** If

$$s \leftarrow c \land a^1 \land a^2 \land \cdots \land a^n,$$

where $c$ is a derived predicate and the $a^i$, $i = 1, \ldots, n$, are recursively defined predicates, then

$$s_j + \delta s_j = s_j + c[\delta a_{j-1}^1 a_j^1 \cdots a_{j-1}^n a_j^n + \delta a_{j-1}^2 a_j^2 \cdots a_{j-1}^n a_j^n + \cdots + a_{j-1}^n a_j^n a_{j-1}^n \delta a_{j-1}^n].$$

**Proof.** The derivation steps used to derive Equation (I) are followed for the proof. \hfill $\square$
I. BALBIN AND K. RAMAMOHANARAO

The equation

$$\delta s_j = \left( c \left[ \delta a_{j-1} a_j^2 \cdots a_j^n + a_{j-1}^1 \delta a_{j-1} a_j^1 \cdots a_j^n \right] \right) - s_j$$

(III)

follows immediately from the theorem. The analysis culminating in Equation (III) clearly demonstrates that by using the differential approach only repeated computations are excluded in the join. Additionally, since we have proved the equivalence between both the naive and differential equations, the least fixed point semantics is preserved. It is important to note that, in computing $\delta s_j$ using equation (III), only the $\delta a_{j-1}^i$ and $a_{j-1}^i$, $i = 1, \ldots, n,$ need be retained during the computation.
