more than 7 days, requiring a blood patch to definitively close. The use of this sealant in selected cases could contribute to reduce the incidence of this complication; if it occurs, the duration is certainly shorter.\textsuperscript{5}

Extrapleural hematoma as a complication of spontaneous pneumothorax

El Hassane Kabiri, MD, Adil Arsalane, MD, Abdelfettah Zidane, MD, and Fouad Atoini, MD, Rabat, Morocco

Extrapleural hematoma (EH) is rare. Only a few cases have been reported under different names: extrapleural, subpleural, or epipleural hematoma. It is potentially lethal because of bleeding risks and ventilatory consequences.\textsuperscript{1} We present a patient with an EH after spontaneous pneumothorax who successfully underwent operation.

Clinical Summary
A 23-year-old man was referred to our department for acute right-sided chest pain and dyspnea. The patient was in a stable hemodynamic state; his arterial pressure was 110/75 mm Hg, heart rate was 110 beats/min, oxygen saturation was 96%, hematocrit value was 28%, and hemoglobin value was 9.3 g/dL. Chest radiography showed an important basal pleural effusion, an apical pneumothorax, and a rounded opacity in the upper right side of the thorax with delineated convex borders suggesting an extrapleural lesion mimicking a benign tumor (Figure 1). Chest drainage removed 1600 mL of blood and revealed air leakage. Thoracic computed tomography scan (Figure 2) confirmed hemothorax and revealed a well-defined, hyperdense mass in the upper right side, measuring 4.5 × 4.0 cm. This mass was not surrounded after contrast injection. This finding was compatible with the diagnosis of hemopneumothorax complicating a pleural benign tumor such as a fibroma. Surgery was indicated both for examination of the thoracic mass and treatment of pneumothorax. Surgery was performed through a mini-posterolateral thoracotomy. A blood collection between the parietal pleura and the endothoracic facia was discovered. The hematoma was evacuated, and a pleural abrasion was performed. The postoperative course was uneventful. The chest tube was removed on day 3. The pathologic study of a fragment of hematoma showed no abnormality.

Discussion
EH can be defined as the presence of blood in the extrapleural space between the parietal pleura and the endothoracic fascia. The presence of blood between the lung parenchyma and the visceral pleural is impossible because of the lack of space between the lung and the visceral pleura. Many causes of EH have been suggested:

traumatic, iatrogenic, spontaneous (as a presentation of ruptured aortic aneurysm), after surgery (particularly coronary surgery), sympathectomy, and pleural thoracoscopic abrasion for spontaneous pneumothorax. EH is created when the blood cannot escape into the pleural cavity because the parietal pleura is still intact. In this case, we think the parietal pleura was minimally ruptured, and the tear was then secondarily closed by close contact with the lung or perhaps an apical adhesion between the parietal and the visceral pleura, leaving a space for the hematoma to form. There is no specific clinical symptom for the diagnosis of EH. In this case, chest pain and dyspnea were related to pneumothorax and hemothorax. Chest radiography and computed tomography scan confirmed the diagnosis showing the pathognomonic sign: displaced extrapleural fat layer and parietal pleura or a pleural lining sign.

EH must be differentiated from other diagnoses such as an encysted pleural effusion, a pleural tumor, a peripheral lung tumor, or a diaphragmatic hernia.

The management of EH depends on its size and cause. Many procedures have been proposed to evacuate the hematoma. When the hematoma is minimal, a simple observation can be proposed as suggested by Poyraz and colleagues. Some authors have discussed the possibility of needle aspiration or drainage, but when the size of hematoma is important a thoracotomy should be performed because of the risk of bleeding and ventilatory and circulatory disturbances. In our case, open thoracotomy was indicated for 3 reasons: the treatment of hemotherax and cause of bleeding, exploration of the pleural mass, and abrasion of the pleura. Some reports have proposed video-assisted thoracic surgery for the management of chest trauma. We think that this method is safe and minimally invasive, although some authors consider it to be a major contraindication for approaching and managing EH.

EH has not received any attention in the literature of chest trauma. EH is a serious condition because of the risk of bleeding, respiratory failure, and death.
