It is widely known that a carcinoid tumor can produce various hormones and is sometimes detected on the basis of the presence of various symptoms caused by the hormones. Cushing syndrome is widely known as one of these symptoms. Many cases of Cushing syndrome have been reported, but occasionally, it is very difficult to detect a tumor that produces adrenocorticotropic hormone (ACTH).1,2 We herein report a rare case of a carcinoid tumor that metastasized to a lymph node, resulting in production of ACTH. Although the lymph node was not enlarged by tumor metastasis, we were able to localize the lymph nodes as the origin of ectopic ACTH production by means of 111In-octreotide scanning. The lymph nodes were completely resected with thoracoscopic surgery, and the symptoms successfully disappeared after the operation.

Clinical Summary

The patient was a 55-year-old woman who had had hypertension since 1991. However, she refused any treatments. In 1996, she reported having facial edema. Hypertension and hypokalemia were detected during examination. Both plasma ACTH and serum cortisol levels were increased (ACTH, 121 pg/mL [normal range, 4.4-48.0 pg/mL]; cortisol, 26.6 μg/dL [normal range, 1.39-24.20 μg/dL]). Increased 17-hydroxycorticosteroids and 17-ketosteroids in the urine were also noted. She was given a diagnosis of Cushing syndrome. Brain magnetic resonance imaging and abdominal computed tomography (CT) failed to detect any tumor mass. The administration of an oral antihypertensive agent was started, and plasma ACTH and serum cortisol levels decreased to normal levels after the operation. Thus, we were not able to obtain proof that this mediastinal mass was the origin of ectopic ACTH secretion. In 2001, an 111In-octreotide scan was performed, which showed a hot spot in the right upper mediastinum (Figure 1, B).3 The ACTH value in the superior vena cava4 was also shown to be higher than that in the peripheral veins. All these findings strongly suggested that the mediastinal mass was an ACTH-producing tumor.

The patient underwent tumor resection with a thoracoscope on May 18, 2001. The tumor seemed to be a solitary, enlarged lymph node, and no other tumor was detected in either the right lung or the mediastinum by means of thoracoscopy. Pathologic examination showed the tumor to be a pair of metastatic lymph nodes (No. 3 [1/6] and No. 4 [4/15]) involved with an atypical carcinoid tumor (Figure 2). Immunohistochemical staining results for ACTH were positive. Examination with a fiberoptic scope targeting the gastrointestinal region, the colon, and the bronchi after the operation failed to find the primary region of the tumor. Plasma ACTH and serum cortisol values decreased to normal levels after the operation.

Discussion

Cushing syndrome related to ectopic ACTH production is associated with a variety of solid tumors (ie, lung cancer, bronchial carcinoid, thymic carcinoid, and gastrointestinal pheochromocytoma). On occasion, the primary lesion of the tumor releasing ACTH cannot be detected. In our case a tumor was detected by means of CT and was confirmed to be an ACTH-producing tumor on the basis of the scintigraphic findings. Pathologic diagnosis was lymph node metastasis of a carcinoid; a primary lesion, however, could not be identified despite thorough examinations. Aniszewski and colleagues5 reported that no tumor was detected in 17 (16%) of 106 cases of ectopic ACTH syndrome. They found bronchial carcinoid to be the most frequent cause of this paraneoplastic disorder. Several reports have also shown the frequent involvement of regional lymph nodes in cases of atypical carcinoid tumor. Our patient had mediastinal nodal involvement but no detectable primary lesion in either the lung or the thymus. After removal, symptoms associated with Cushing syndrome disappeared, and the value of the ACTH level returned to normal. Thus, it is suggested that the lymph nodes removed by means of thoracoscopic surgery were the major origin of ectopic ACTH in our case. There have been some reports of Tx N2 M0 lung cancer. Thus, we concluded that this case was a carcinoid tumor with Tx N2 M0 stage IIIA disease. However, we could not find any reports of Tx N2 M0 carcinoid tumors. Careful follow-up for detection of a possible occult primary pulmonary lesion is required.
