Multi-Objective Infinite-Horizon Discounted Markov Decision Processes

D. J. White

Submitted by Richard Bellman

1. INTRODUCTION

In a recent paper, Daellenbach and de Kluyver [1] discussed a multi-objective routing problem, using an extension of Bellman's [6] successive-approximations equation for vector-minimisation problems. This approach is also studied in White [2, p. 190], Henig [3], and Hartley [4]. The extension of the usual method of successive-approximations method works, in effect, because only a finite number of iterations are required, and only a finite number of actions are allowable at each iteration. For other problems the situation is not so straightforward.

In this paper we shall examine the extended method in the context of a class of infinite-horizon discounted Markov decision processes. The alternative weighting-factor method is fully discussed in Hartley [7] for this class of problems, and in White [10] for the multi-objective routing problem referred to earlier. We shall make the following assumptions, some of which may be relaxed (e.g., finite-state requirements), given appropriate measurability conditions.

There is a finite set \( I \) of states, \( i = 1, 2, ..., N \); for each state \( i \in I \), there is a compact-action set \( K_i \); for each \( i \in I \), \( k \in K_i \), there is a single-stage loss vector \( f^k_i \in \mathbb{R}^m \), continuous on \( K_i \), with components \( f^k_{il} \), \( l = 1, 2, ..., m \), and a transition probability \( p^k_{ij} \), continuous on \( K_i \), from state \( i \) to state \( j \); there is a discount factor \( \rho \), \( 0 \leq \rho < 1 \).

A decision rule \( \delta \) tells us which action in \( K_i \) to take for any state \( i \in I \) which we may realise. The set of all such decision rules \( \Delta \) is compact. A policy \( \gamma \) is a sequence of such decision rules, \( (\delta_1, \delta_2, ..., \delta_n, ...) \), which tells us, at the beginning of the appropriate period, which action to take when we know the state \( i \in I \) at the beginning of that period. If the sequence is infinite, then the set of all such sequences is \( \Gamma \). If the sequence contains \( n \) members, we let \( \Gamma^n \) be the set of all such sequences.

For each \( \delta \in \Delta \), there will be a transition probability matrix \( P^\delta \) with the
\((i,j)\)th element written as \([P^0]_{ij}\), a general convention we shall use. For each \(\gamma \in \Gamma\), or \(\gamma \in \Gamma^n\), we shall have expected discounted vector-objective function values as given below.

\[
v^\gamma_i = \sum_{s=0}^{\infty} \rho^s \sum_{j=0}^{N} \left( \prod_{t=0}^{s} P^{\delta_{s+1}}_{ij} \right) f_{j}^{\delta_{s+1}(j)},
\]

(1)

\[
v^\gamma_i = -\sum_{s=0}^{n} \rho^s \sum_{j=1}^{N} \left( \prod_{t=0}^{s} P^{\delta_{s+1}}_{ij} \right) f_{j}^{\delta_{s+1}(j)},
\]

(2)

\[
v^\gamma_i = 0,
\]

(3)

We shall use \(v^\gamma_i\), whether or not \(\gamma \in \Gamma\) or \(\gamma \in \Gamma^n\), and the usage will be seen from the context. We shall also not differentiate, in typeface, between vectors in \(\mathbb{R}^p\), for any \(p\), and scalars. Again the context will make the usage clear.

The sets of all such vectors given by (1) or (2), (3), are \(V_i\) and \(V^n_i\), respectively.

Let us now consider the efficiency aspects. For any set, \(X \subseteq \mathbb{R}^p\), we let the efficient set be defined as follows:

\[
\mathcal{E}(X) = \{x \in X : y \leq x \rightarrow y = x\}.
\]

For future use, we note that we adopt the standard convention for inequalities, viz. if \(x, y \in \mathbb{R}^p\), then \(y \leq x \Leftrightarrow y_i \leq x_i, \forall i; y \leq x \Leftrightarrow y \leq x, y \neq x; y < x \Leftrightarrow y_i < x_i, \forall i; x = y \Leftrightarrow x_i = y_i, \forall i \leq x\).

In this paper we shall be concerned with, in particular, \(\mathcal{E}(V_i)\) and \(\mathcal{E}(V^n_i)\), and the vector value method of successive approximations given below (see Theorem 2 for detailed analysis and definitions).

\[
n \geq 1, \quad W^n_i = \mathcal{E} \left( \bigcup_{k \in K_i} \left( f^k \oplus \rho \sum_{j=1}^{N} p^k_{ij} W^{n-1}_j \right) \right), \quad \forall i \in I
\]

\[
n = 0, \quad W^0_i = \{0\}, \quad \forall i \in I.
\]

It will be shown, in particular, that \(\{\mathcal{E}(V^n_i)\}\) is the unique solution to these equations. Now, for scalar-valued Markov decision processes, the limiting solution, as \(n \to \infty\), to these equations would be the unique solution to the infinite-horizon problem, giving the minimal-expected discounted value, over \(\Gamma\). Unfortunately this limiting result does not carry over to vector-valued Markov decision processes. Thus, consider the following example:

\(I = \{1, 2, 3\}; \quad K_1 = \{1, 2\}, \quad K_2 = \{1\}, \quad K_3 = \{1\}; \quad p^1_{11} = 1, \quad p^2_{11} = 1, \quad p^3_{11} = 1, \quad p^1_{21} = 0, \quad p^3_{21} = 0, \quad p^1_{31} = 0, \quad p^3_{31} = 0, \quad \text{otherwise}; \quad f^1_1 = (1, 1 + \rho^{-1}), \quad f^2_1 = (2, \rho^{-1}), \quad f^3_1 = (1, 1), \quad f^3_2 = (2, \rho^{-1}). \) We then have
DISCOUNTED MARKOV DECISION PROCESSES

\[ n \geq 1, \quad \mathcal{E}(V^n) = \{u^n, v^n\}, \]

\[ u^n = ((1 - \rho^n)/(1 - \rho), (1 - \rho^n+1)/(\rho(1 - \rho))), \]

\[ v^n = (2(1 - \rho^n)/(1 - \rho), (1 - \rho^n)/\rho(1 - \rho)), \]

\[ \mathcal{E}(V_1) = \{u\}, \quad u = (1/(1 - \rho), 1/\rho(1 - \rho)). \]

Hence, the limit of the sequence \{v^n\} is not efficient in \( V_1 \), but each of its members is efficient in \( V^n_1 \), for each \( n \).

Theorem 1 specifically deals with this problem and, in effect, says that \( \mathcal{E}(V_i) \) is identical with the efficient set of the limit points, which gives the usual scalar-valued result when \( m = 1 \).

In our theoretical analysis we merely assume \( \Lambda \) to be compact. In Hartley [7], \( K_i \) is the set of all probability distributions over a finite set of actions, and this makes \( \Lambda \) compact. In Hartley's case, he shows that, when finding \( \mathcal{E}(V_i) \), we may restrict ourselves to stationary members of \( \Gamma \), i.e., those \( \gamma \in \Gamma \) which can be expressed as an infinite repetition of a single \( \delta \in \Delta \). This is useful if one is using a weighting-factor approach to find \( \mathcal{E}(V_i) \). In our case, we are not studying the weighting-factor approach, and since our computations will involve finite iterations in arriving at some suitable termination point, we may have a nonstationary sequence \( \gamma \in \Gamma^n \) at the termination point. We shall not study the stationary problem for the general compact \( \Lambda \), but will comment on this when \( \#\Delta < \infty \).

Let us consider the stationary/nonstationary issue via an example, viz. \( I = \{1\}; K_i = \{1, 2, 3\}; \Lambda = \{\delta_1, \delta_2, \delta_3\}, \) where \( \delta_q(1) = q, \forall q; f^1 = (3, 0), f^2 = (0, 3), f^3 = (2, 2) \). Then, if \( \gamma = (\delta_q, \delta_{q'\ldots}, \delta_{q\ldots}) \) we have the following:

\[ v^{\gamma}_{\mathcal{I}} = (3/(1 - \rho), 0), \quad v^{\gamma}_{V_i} = (0, 3/(1 - \rho)), \quad v^{\gamma}_{V} = (2/(1 - \rho), 2/(1 - \rho)). \]

If \( \gamma = (\delta_1, \delta_2, \delta_1, \delta_2\ldots\ldots) \), i.e., \( \delta_1, \delta_2 \) alternating, we have the following:

\[ V^{\gamma}_{\mathcal{I}} = (3/(1 - \rho^2), 3\rho/(1 - \rho^2)). \]

We then see that \( v^{\gamma}_{\mathcal{I}} < v^{\gamma}_{V_i} \) if \( \rho > \frac{1}{2} \). At the same time, had we been interested only in stationary policies, none of \{\( v^{\gamma}_{V_i} \)\} dominates any other member of \{\( v^{\gamma}_{V_i} \)\}, but \( v^{\gamma}_{\mathcal{I}} \) is dominated by \( v^{\gamma}_{V_i} \). Clearly, it would be inadvisable to restrict oneself to stationary policies in this case.

For the same example, if \( \rho \) is small enough, it is possible to show that \( \mathcal{E}(V_i) = V_1 \), and again it would be inadvisable to restrict oneself to nonstationary policies in this case, if all members of \( \mathcal{E}(V_i) \) are required.

Finally, if it is admissible in principle to extend \( K_i \) to all probability mixtures over \( K_i \), and correspondingly, extend \( \Lambda \), we could get wrong results by confining ourselves to the original \( \Lambda \) for efficiency purposes. Thus, if \( k_i \) is an equiprobability mixture of \( k_1 (=1) \), and \( k_2 (=2) \), and \( \gamma = (\delta, \delta\ldots, \delta\ldots) \),
where $\delta$ uses action $k_4$ always, we shall have $v'_1 < v''_1$, whereas $\gamma_1$ would be undominated in the original problem.

The net effect is that if $A$ is obtained by taking probability mixtures over a finite number of actions, for each state, we must ensure that our calculations cover these probability mixtures, and, at the same time, we must cater for nonstationary policies, for the general compact $A$, although, in Hartley’s case, this is not necessary.

Let us now consider our theoretical results.

2. THEORETICAL RESULTS

Let us first define the terms we shall use, in addition to those already defined.

$M$: max $\max_i \sup_{1 < j < m} \sup_{k \in k_i} \left| f_{ij} \right|$. \\
$L_i^k$: the set of limit points of all sequences $\{v_i^n\}$, with $v_i^n \in V_i^n$, for all $n$ in the sequence.

$\mathcal{L}_i^k$: the set of limit points of all sequences $\{v_i^n\}$, with $v_i^n \in \mathcal{S}(V_i^n)$ for all $n$ in the sequence.

Convergence in all cases is in the usual sup-norm sense. We may now establish the following results.

**Lemma 1.**

$L_i^k = V_i$, $\forall i$.

**Proof.** Let $v \in V_i$. Then there is a $\gamma \in \Gamma$ such that $v_i = v'_i$, and $v'^i$ is the limit of a sequence, $\{v_i^n\}$, with $v_i^n \in V_i^n$, $\forall i$, given by

$$n \geq 1, \quad v_i^n = f_i^{\delta_n(j)} + \rho \sum_{j=1}^{N} p_{ij}^{\delta_n(j)} v_{ji}^{n-1}$$

(4) 

$$v_i^0 = 0$$

(5) 

for some sequence $\{\delta_n\} \subseteq \Delta$.

Hence $V_i \subseteq L_i^k$, $\forall i$.

Now let $v \in L_i^k$. Then $v$ is a point of convergence of a subsequence, $\{v_i^n\}$, $n \in \mathcal{N}_i$, and $v_i^n \in V_i^n$, $\forall n \in \eta_i$. There also exists, for each such $n \geq 1$, $\delta_i \in \Delta$, and a set $\{v_{ji}^{n-1}\}$, $j \in I$, with $v_{ji}^{n-1} \in V_{ji}^{n-1}$, $\forall j$, such that

$$v_i^n = f_i^{\delta_i(j)} + \rho \sum_{j=1}^{N} p_{ij}^{\delta_i(j)} v_{ji}^{n-1}.$$ 

(6)
Since $A$ is compact, there exists a subsequence $\mathcal{N}_2 \subseteq \mathcal{N}_1$, and a $\delta^1 \in A$ such that $\{\delta^1_n\}$ converges to $\delta^1$ as $n \to \infty$ in $\mathcal{N}_2$. Let us now consider $n \in \mathcal{N}_2$, and the set $\{v^n_j\}$. We see that, for each $j \in I$, $v^n_j$ may likewise be expressed in a form similar to (6), in terms of a set $\{v^{n-2s}_j\}$, $s \in I$, and some $\delta_{n,n-1} \in A$. Again we may choose a subsequence $\mathcal{N}_3 \subseteq \mathcal{N}_2$, and a $\delta^2 \in A$, such that $\delta_{n,n-1}$ converges to $\delta^2$ as $n \to \infty$ in $\mathcal{N}_3$. We may repeat the process $r$ times to produce a sequence of subsequences $\mathcal{N}_r$ with $\mathcal{N}_{r+1} \subseteq \mathcal{N}_r$, with the property that, for any given $\varepsilon > 0$, and any $r \geq 2$, for $n$ sufficiently large in $\mathcal{N}_r$, we have

$$v^n_i - \sum_{s=0}^{r-2} p^s \sum_{j=1}^N \left[ \prod_{l=0}^{s} P^j \right] f^{\delta^s+1(j)} - p^{r-1} \sum_{j=1}^N \left[ \prod_{l=0}^{r-1} P^j \right] z_j \leq \varepsilon, \quad \forall i, (7)$$

where $\{\delta^i\} \subseteq A$, $P^{\delta_0}$ is equal to the unit matrix, and $z_j \in V^{n-r+1}_j, \forall j$. Since $|z_j| \leq M/(1-p)$, $\forall j, l$, the last term inside the modulus signs in (4) may be made arbitrarily small if $r$ is made large enough. Since $\varepsilon$ is arbitrary, we obtain $v^n_i = \lim_{n \to \infty} [v^n_i] = u$, where $\sigma = (\delta^1, \delta^2, \ldots, \delta^r, \ldots)$.

Hence $L^n_1 \subseteq V_1$.

**Lemma 2.**

(i) If $v \in V_i$, there exists a $u \in \mathcal{G}(V_i)$ with $u \leq v$.

(ii) If $v \in V^n_i$, there exists a $u \in \mathcal{G}(V^n_i)$ with $u \leq v$.

(iii) If $v \in L^n_1$, there exists a $u \in L^n_1$ with $u \leq v$.

**Proof.** (i) This follows from White [5, Theorem 4], if we can show that $V_i$ is compact, and the set $S_i(v) = \{u \in V_i : u \leq v\}$ is closed, $\forall v \in V_i$. Clearly, $V_i$ is bounded. Now let $\{u^\alpha\}$ be a sequence of points in $V_i$, converging to a point $u \in \mathbb{R}^m$. Since $v \in V_i$, and $\{u^\alpha\} \subseteq V_i$, we have $v = v^\alpha$, and $u^\alpha \leq v^\alpha$, $\forall \alpha$, and $\gamma \in \Gamma$, $\{\gamma^\alpha\} \subseteq \Gamma$. Let $\delta^\alpha$ be the first decision rule in $\gamma^\alpha$. We may choose a subsequence $\mathcal{A}^\alpha$ such that $\{\delta^\alpha\}$ converges to some $\delta^1 \in A$ as $\alpha \to \infty$ in $\mathcal{A}^\alpha$. We then repeat the same sort of procedure as in Lemma 1, and produce a sequence of subsequences $\mathcal{A}_r$ such that we have a similar result to that in (8), and since each limit point of $\{u^\alpha\}$, $\alpha \in \mathcal{A}_r$, must be the same as $u$, we deduce that $u = v^\gamma$. This proves that $V_i$ is closed. Now, if $u^\alpha \leq v$, $\forall \alpha$, it follows that $u \leq v$, and, together with the closure of $V_i$, it follows that $S_i(v)$ is closed.

(ii) In line with the proof in (i), all we need to show is that $V^n_i$ is closed, since the other requirements follow as in (i). Let $\{u^\alpha\}$ be a sequence of points in $V^n_i$, converging to a point $u \in \mathbb{R}^m$. For each $\alpha$, there exists a $\gamma^\alpha \in \Gamma^\alpha$ such that $u^\alpha = v^{\gamma^\alpha}_i$. We may now choose a subsequence $\mathcal{A}^\alpha$, such that if $\delta^\alpha$ is the first decision rule in $\gamma^\alpha$, $\{\delta^\alpha\}$ converges to some $\delta^1 \in A$. We
may repeat the same sort of analysis as in (i), but in this case we only have $n$ subsequences, and can set $r_j = 0$, $\forall j \in I$, in the corresponding expression to (7) when $r = n$, and the required result follows.

(iii) Let $v \in L_r^r$. Then there exists a subsequence $\{v^n\}$, with $v^n \in V^n$, $\forall n \in \mathcal{N}$, and $\{v^n\}$ converges to $v$. From part (ii), there exists a subsequence $\{u^n\}$, with $u^n \leq v^n$, and $u^n \in \mathcal{E}(V^n)$, $\forall n \in \mathcal{N}$. Since $\bigcup_n V^n$ is bounded, there exists a subsequence $\mathcal{N} \subseteq \mathcal{N}$ such that $\{u^n\}$ converges to some point $u$ in $\mathbb{R}^m$ for $n \in \mathcal{N}$, and, by definition, $u \in L_r^r$. Clearly, $u \leq v$ and the requisite result follows.

We may now prove our main theorems.

**THEOREM 1.**

$$\mathcal{E}(L_r^r) = \mathcal{E}(V_r), \forall i.$$  

**Proof.** Let $v \in \mathcal{E}(L_r^r)/\mathcal{E}(V_r)$. Then $v \in L_r^r$, and, from Lemma 1, there is a $\sigma \in \Gamma$, such that $v = v_\sigma$. Since $v \in \mathcal{E}(V_r)$, there is a $\gamma \in \Gamma$, such that $v_\gamma \leq v$. Now $v_\gamma$ is the limit of a sequence $\{v^n_\gamma\}$, given by (4), (5), with $v^n_\gamma \in V^n$, $\forall n$. From Lemma 2, for each $n$ there exists a $u^n_\gamma \in \mathcal{E}(V^n)$ such that $u^n_\gamma \leq v^n_\gamma$ (where we replace $v^n_\gamma$ by $v^n$, for a specific $i$, for notational convenience). Since $\bigcup_n V^n$ is bounded, there exists a subsequence $\mathcal{N} \subseteq \mathcal{N}$ such that $u_\gamma \in \mathcal{E}(V^n)$ for $n \in \mathcal{N}$. From Lemma 1, since $u \in L_r^r$, there exists a $\tau \in \Gamma$ such that $u = u_\tau$. Then, since clearly, $u \leq v_\gamma \leq v = v_\sigma$, we have $v_\gamma \leq v_\sigma$. Since $v_\gamma \in L_r^r$, by construction, and $v_\sigma \in \mathcal{E}(L_r^r)$, by assumption, we have a contradiction.

Hence $\mathcal{E}(L_r^r) \subseteq \mathcal{E}(V_r), \forall i$.

Now let $v \in \mathcal{E}(V_r)/\mathcal{E}(L_r^r)$. Then there is a $\sigma \in \Gamma$ such that $v = v_\sigma$. From Lemma 1, $v \in V_\sigma = L_r^r$, and, from Lemma 2, there is a $u \in L_r^r$, with $u \leq v$. Then $u \in L_r^r \subseteq L_r^r = V_r$, however, and hence we must have $u = v$, i.e., $v \in L_r^r$. Since $v \in \mathcal{E}(L_r^r)$, there is a $w \in L_r^r$ with $w \leq v$. Then $w \in L_r^r \subseteq L_r^r = V_r$, and this contradicts $v \in \mathcal{E}(V_r)$.

Hence $\mathcal{E}(V_r) \subseteq \mathcal{E}(L_r^r)$.  

**THEOREM 2.** For all $n \geq 1$, $\{\mathcal{E}(V^n_r)\}$ is the unique solution $\{W^n_i\}$ to the following equation, which is in $\oplus$ sum-set form.

$$n \geq 1, \quad W^n_i = \mathcal{E} \left( \bigcup_{k \in K_i} \left( f_i^k \oplus \sum_{j=1}^N p_{ij}^k W_j^{n-1} \right) \right), \quad \forall i \in I \quad (8)$$

$$n = 0, \quad W^0_i = \{0\}, \quad \forall i \in I. \quad (9)$$

**Proof.** The theorem is clearly true for $n = 0$. Let us assume that it is true for $n - 1$, for some $n \geq 2$.  

...
Let \( v \in \mathcal{S}(V^n_1) \). Then there is a \( y \in \Gamma^n \) such that \( v = v^n_1 \). If \( \delta_n \) is the first decision rule in \( y \), we shall obtain, as in (4), the following equation for some set \( \{ v^n_{j-1} \}, j \in I \), with \( v^n_{j-1} \in V^n_{j} \), \( \forall j \in J \).

\[
v = f_i + \sum_{j=1}^{N} p_{ij} v^n_{j-1}.
\] (10)

From Lemma 2, for each \( j \in I \), there is a \( u^n_{j-1} \in \mathcal{S}(V^n_{j-1}) \) such that
\[
u^n_{j-1} \leq v^n_{j-1}.
\]

Let
\[
w = f_i + \sum_{j=1}^{N} p_{ij} u^n_{j-1}.
\] (11)

Then \( w \in V^n_1 \), and \( w \leq v \). Hence \( w = v \). Since by assumption, \( \mathcal{S}(V^n_{j-1}) \) is the unique solution \( W^n_{j-1} \) to (8), (9), for \( n - 1 \),
\[\mathcal{S}(V^n_1) \subseteq W^n_i, \quad \forall i \in I.
\]

Now let \( w \in W^n_i \). Then there is a \( y \in \Gamma^n \), such that \( v = v^n_1 \), and if \( \delta_n \) is the first decision rule in \( y \), we have, again, expression (10), with \( v^n_{j-1} \in W^n_{j} \), \( \forall j \in J \). By assumption, \( v^n_{j-1} \in \mathcal{S}(V^n_{j-1}) \), \( \forall j \in J \). Now suppose \( w \notin \mathcal{S}(V^n_1) \). Then there is a \( v \in \Gamma^n \), such that \( v \leq w \), and by Lemma 2, we may assume that \( v^n_1 \in \mathcal{S}(V^n_1) \). Hence, from the first part, we have \( v^n_1 \in W^n_1 \). This is not possible since \( W^n_1 \) is an efficient set, and we cannot have \( v^n_1 \leq w \).

Hence \( W^n_1 \subseteq \mathcal{S}(V^n_1), \forall i \in I.\)

The uniqueness of \( \{ V^n_i \} \) as a solution to (8), (9) is obvious.

**Lemma 3.** Let \( f_i \leq 0, \forall i \in I, k \in K_i \). Then, for each \( i \in I, \) \( n \geq 1 \), and each \( v \in \mathcal{S}(V^n_{i-1}) \) there is a \( u \in \mathcal{S}(V^n_1) \) with \( u \leq v \).

**Proof.** The lemma is clearly true for \( n = 1 \). Let us assume it is true for \( n - 1 \), for some \( n \geq 2 \), and let \( v \in \mathcal{S}(V^n_1) \). Then, for some \( k \in K_i \) and some set \( \{ w_j \}, j \in I \), with \( w_j \in V^n_{j-1} \), for all such \( j \), we have
\[
v = f_k + \sum_{j=1}^{N} p^k_{ij} w_j.
\] (12)

Let
\[
t = f_k + \sum_{j=1}^{N} p^k_{ij} z_j,
\] (13)

where by assumption, we may choose \( z_j \in \mathcal{S}(V^n_{j-1}) \) with \( z_j \leq w_j \), for all \( j \in I \) and \( t \in V^n_1 \).

Then, clearly, \( t \leq v \). From Lemma 2, there is a \( u \in \mathcal{S}(V^n_i) \) with \( u \leq t \), and the requisite result follows.
We may now prove Theorem 3, where $L_i^c$ is now the set of all limit points of monotonic-decreasing sequences \{v^n\}, i.e., such that $v^n \leq v^{n-1}$, for $n \geq 1$, and $v^n \in (V_i^n)$, for $n \geq 1$.

**THEOREM 3.**

$\mathcal{E}(L_i^c) \subseteq \mathcal{E}(V_i)$.

**Proof.** This follows in a similar manner to that of Theorem 1, replacing $L_i$ by $L_i^c$, and noting that, by virtue of Lemma 3, the sequence \{u^n\} may be chosen so that $u^n \leq u^{n-1}$, for all $n \geq 1$, and hence, that the limit $u$ is in $L_i^c$.

**CONCLUDING REMARKS**

The basic purpose of the paper is to show that, in principle, the vector generalisation of the usual scalar method of successive approximations may be used to tackle the problem of finding efficient solutions for infinite-horizon discounted Markov decision processes. The introductory section indicates some of the difficulties one meets, which do not arise in the scalar-valued case.

The analysis provides a framework for an extension of bound, and elimination of action, analyses as described, in general, in White [8], and clearly considerable development is needed if this approach is to be used in a manner analogous to the established approach for scalar-valued problems. Although there is the problem of explosion, as we increase the value of $n$, the scalar analyses have indicated that $n$ need not be too large before acceptable approximations are reached.

There is still the problem of interpreting the use of the $\mathcal{E}(V_i^n)$ analysis to obtain approximations to $\mathcal{E}(V_i)$.

First of all, if $v^n = v_i^n$, $u^n = v_i^n$, for some $\gamma$, $\tau \in I^n$, we know that neither of $v^n$ or $u^n$ dominates each other. We are seeking, however, for the infinite-horizon problem, policies in $\Gamma$. If $\gamma' = (\gamma, \sigma)$, $\tau' = (\tau, r)$, where $\sigma, r \in \Gamma$, it is easily seen that $\|v^n - v_i^n\| \leq \rho^n M/(1 - \rho)$, and $\|u^n - v_i^n\| \leq \rho^n M/(1 - \rho)$, and hence, although either $v_i^n$ or $v_i^n$ may dominate each other, they can be made arbitrarily close to $v^n$ and $u^n$, respectively, which do not dominate each other, if $n$ is large enough.

Secondly, if the sequence \{v^n\}, $v^n \in \mathcal{E}(V_i^n)$, has a limit point $v$, then either $v \in \mathcal{E}(V_i)$, in which case $v^n$ is close to a member of $\mathcal{E}(V_i)$ if $n$ is large enough, or $v \notin \mathcal{E}(V_i)$, in which case, if $u \in \mathcal{E}(V_i)$ and $u \leq v$, there is a $u^n \in \mathcal{E}(V_i^n)$ close to $u$, which does not dominate $v^n$. That is, there are points in $\mathcal{E}(V_i^n)$ close enough to $v$, which are not dominated by some points in $\mathcal{E}(V_i^n)$ close enough to $u$. 
Hence our *approximation* must be defined in terms of the above concepts combined, which show that if \( n \) is large enough, and we use the policies \( y' \) or \( r' \) as determined above, even though the one limit point may dominate another, and either \( v' \) or \( v' \) may dominate each other, there are points in \( \mathbb{R}^m \) which are close enough to the limit points or to \( v' \) and \( v' \), which do not dominate each other.

In using Theorem 2 there is the problem of picking out convergent sub-sequences. For monotone decreasing sequences we have no problem, since they will converge in any case. Hence, Theorem 3 may be useful. It will, of course, only produce, in general, a subset of \( \mathcal{E}(V_i) \). All Markov decision processes can be transformed to ones in which \( f_{ik}^* \leq 0, \forall i \in I, k \in K_i \) (see White [2]).

Finally, we have only been concerned with finding the individual \( \mathcal{E}(V_i) \); and associated policies, or approximating policies. We might be interested in policies \( y \in I \), such that \( v_i' \in \mathcal{E}(V_i), \forall i \in I \). In this case, if \( \lambda \in \mathbb{R}^m, \lambda > 0 \), it is well known that, if \( \#A < \infty \), if we minimise \( [\lambda v_i'] \), where \( y \) is a repeated application some \( \delta \), over \( \Delta \) (see White [9]), then \( v_i' \in \mathcal{E}(V_i) \) for any such optimisers \( \delta \). Now, if \( P^k \) has no transient states, for any \( \delta \in \Delta \), then if \( y \) minimises \( [\lambda v_i'] \) over \( \Delta \), for some \( i \), \( y \) will also minimise \( [\lambda v_i'] \) over \( \Delta \) for all \( i \). Hence, in this case, the weighting-factor approach will produce uniformly efficient policies, i.e., for all \( i \in I \). Hartley [7] deals with the weighting-factor approach when \( \Delta \) is the convex hull of a finite set of policies as described in Section 1.
