**Abstract** In the presented work the thermal, theoretical (DFT) and spectroscopic (IR, Raman, NMR) properties of alkali metal complexes with quinolinic acid (2,3-pyridinedicarboxylic acid) and dipicolinic acid (2,6-pyridinedicarboxylic acid) were studied. The IR and Raman spectra were registered and analyzed in the range of 400–4000 cm<sup>-1</sup>. <sup>1</sup>H NMR and <sup>13</sup>C NMR spectra of analyzed compounds have been registered and assigned. The electronic charge distribution for the studied acids and their salts with lithium, sodium and potassium was calculated. All the calculations were done in the frame of density functional theory (DFT) using 6-311 + + G(d,p) basis set. The thermal decomposition of the analyzed compounds was done.

## 1. Introduction

In this paper we decided to focus on the physicochemical properties and thermal decomposition of the quinolinic acid (2,3-pyridinedicarboxylic, 2,3-PDA) and dipicolinic acid (2,6-pyridinedicarboxylic, 2,6-PDA). These acids are two of the six

pyridinedicarboxylic acid isomers. They are ligands of high biological importance. Quinolinic acid is one of the final products of tryptophan transformation in the kynurenine pathway (Fig. 1). The kynurenine pathway is a major route of tryptophan catabolism, resulting in the production of nicotinamide adenine dinucleotide (NAD<sup>+</sup>) and several neuroactive intermediates (Fig. 1) (Heyes et al., 1992). In the metabolic pathway there are also produced other pyridinecarboxylic acids (picolinic acid and nicotinic acid, studied in our earlier works) that play important roles in the body. In pathological conditions, the elevated concentration of quinolinic acid causes strong neurotoxicity (Pérez-De La Cruz et al., 2007). Quinolinic acid neurotoxicity is supposed to be caused partly by the over-excitation of the N-methyl-D-aspartate (NMDA) receptor and partly by elevated levels of cytotoxic reactive oxygen species (ROS) in the brain tissue (Kubicova et al., 2015). There is accumulating evidence that quinolinic acid is involved

**Figure 1** Kynureine pathway (Chen et al., 2011).

in the neurotoxicity associated with several inflammatory brain diseases such as Alzheimer's (Guillemin and Brew, 2002; Guillemin et al., 2003, 2005; Rahman et al., 2009), Parkinson's (Zinger et al., 2011), motor neuron (Chen et al., 2010), Huntington's diseases (Stoy et al., 2005; Bruyn and Stoof, 1990) and multiple sclerosis (Hartai et al., 2005; Lim et al., 2010). Dipicolinic acid and its salts are important components of the bacterial spores. These substances increase the resistance of the spores to UV radiation (Powell and Strange, 1953; Slieman and Nicholson, 2001) and improve the stability of bacterial spores (the aerobic *Bacillus* and anaerobic *Clostridium*).

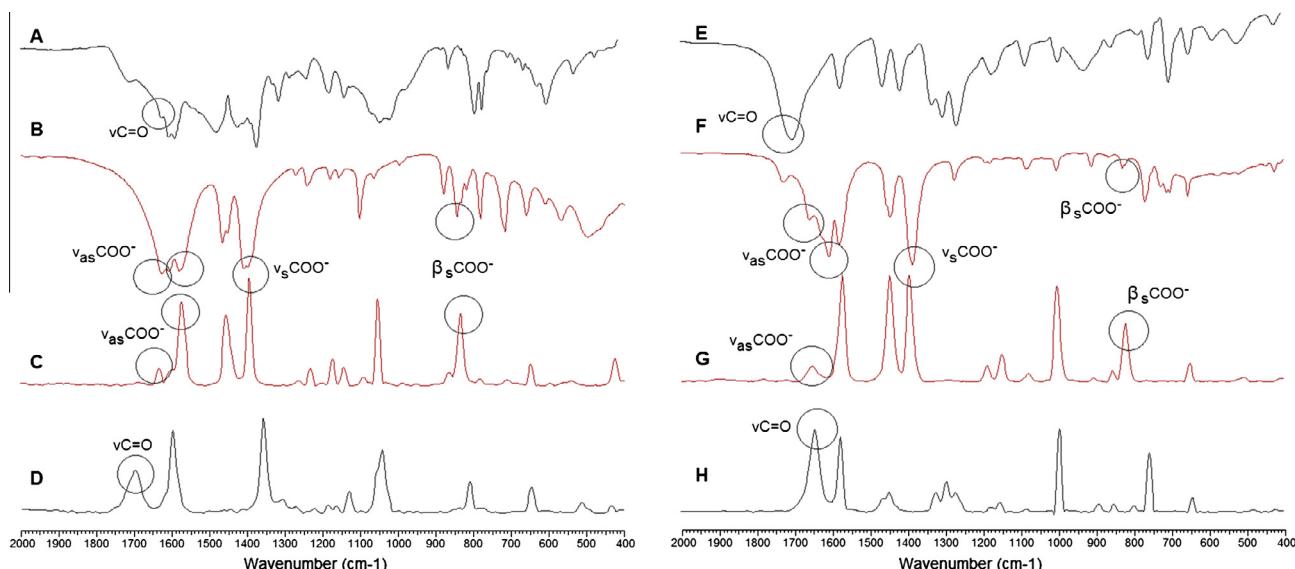

Pyridinecarboxylic and dipyridinecarboxylic acids are potent natural chelators. The presence of nitrogen in the pyridine ring can create a stable connection chelate of N, O-metal coordination of different types. In our previous work we studied complexes of some pyridinecarboxylic acid (nicotinic, isonicotinic and picolinic) isomers with various metals. We analyzed the effect of metal on the change in the electronic charge distribution under the influence of ligands complexing different metals, and antimicrobial properties of complexes. Examined were, *inter alia*, pyridinecarboxylic acid salts of alkali metals (lithium, sodium, potassium, rubidium and cesium). Alkali metals destabilized the electronic system of the aromatic ring in the analyzed acids (Lewandowski et al., 2005; Koczoń et al., 2006; Świderski et al., 2006; Kalinowska et al., 2007). It was shown that the degree of destabilization depended on the type of metal, and the position of the nitrogen in the pyridine ring relative to the carboxyl groups. Spectroscopic

studies (FT-IR, FT-Raman, NMR) and theoretical calculations (electron charge distribution) showed that the alkali metal cations disrupted the electronic system of pyridinecarboxylic acid, and the perturbation increased in the following order: Li → Na → K → Rb → Cs (Lewandowski et al., 2005; Koczoń et al., 2006; Świderski et al., 2006; Kalinowska et al., 2007). Based on these studies, we have found that alkali metals have less impact on the electronic system of picolinic and nicotinic than of isonicotinic acid. Alkali metals to the highest degree interfered with the aromatic system of nicotinic acid. In the present study we compare the effect of alkali metals on the electron system of two other ligands – pyridinecarboxylic acids (dipicolinic and chinolinic acids); the thermogravimetric properties of the salts are tested (see Fig. 2).

## 2. Material and methods

### 2.1. Sample preparation

The alkali metal salts of 2,3-pyridinedicarboxylic and 2,6-pyridinedicarboxylic acids were prepared by dissolving appropriate weighed amount of particular acids in aqueous solution of alkali metal hydroxides in a stoichiometric ratio ligand:metal – 1:2. 0.1 mol of 2,3-pyridinedicarboxylic acid,

**Figure 2** FTIR spectra A, B, E, F and Raman spectra (C, D, G, H) for 2,3-pyridinedicarboxylic acid (A, D) and sodium salt (B, C); 2,6-pyridinedicarboxylic acid (E, H) and sodium salts (F, G).

was added to 20 mL of the previously prepared metal hydroxide solutions having a concentration of 0.1 M. The synthesis of alkali metal salts of 2,6-pyridinedicarboxylic acid was performed in a similar manner. The mixtures were heated on a steam bath with stirring until the acid dissolved in sodium hydroxide. Then, water was evaporated on a water bath and dried in an oven at 70 °C for 24 h. All chemicals were purchased from Sigma–Aldrich.

## 2.2. Measurement and calculation

The FT-IR spectra were recorded with an Alfa (Bruker) spectrometer within the range of 400–4000 cm<sup>-1</sup>. Samples in the solid state were measured in KBr matrix pellets and in ATR technique. FT-Raman spectra of solid samples were recorded in the range of 400–4000 cm<sup>-1</sup> with a MultiRam (Bruker) spectrometer. The resolution of the spectrometer was 1 cm<sup>-1</sup>. The <sup>1</sup>H and <sup>13</sup>C NMR spectra of D<sub>2</sub>O solution of studied compounds were recorded with a Bruker Avance II 400 MHz unit at room temperature. TMS was used as an internal reference. To calculate optimized geometrical structures of 2,3-, 2,6-pyridinedicarboxylic acid and lithium, sodium and potassium salts quantum-mechanical methods were used: density functional (DFT) hybrid method B3LYP with non-local correlation provided by Lee–Young–Parr expression. All calculations were carried out with functional base 6-311++G(d,p). Calculations were performed using the Gaussian 09 (Frisch et al., 2009) package. Experimental spectra were interpreted in terms of DFT method calculations in B3LYP/6-311++G(d,p) level and literature data (McCann and Laane, 2008; Karabacak et al., 2015). Theoretical wave numbers were scaled according to the formula:  $v_{scaled} = 0.98 \cdot v_{calculated}$  for B3LYP/6-311++G(d,p) level method (Rode et al., 2001). Chemical shifts ( $\delta_i$ ) were calculated by subtracting the appropriate isotopic part of the shielding tensor ( $\sigma_i$ ) from that of TMS ( $\sigma_{TMS}$ ):  $\delta_i = \sigma_{TMS} - \sigma_i$  (ppm). The isotropic shielding constants for TMS calculated using the DFT method at the same level of theory were equal to 31.8201 ppm and

182.4485 ppm for the <sup>1</sup>H nuclei and the <sup>13</sup>C nuclei, respectively. The products of dehydration and decomposition processes were determined from the TG curves. Thermogravimetric analysis (TGA) was performed on a Mettler Toledo Star TGA/DSC1 unit. Argon was used as a purge gas (20 ml min<sup>-1</sup>). Samples between 2 and 4 mg were placed in aluminum pans and heated from 50 °C to 900 °C with a heating rate of 10 °C/min.

## 3. Results and discussion

### 3.1. IR and Raman Spectra

The wave numbers, intensities and assignments of the bands occurring in the IR (KBr and ATR) and Raman spectra of 2,3-pyridinedicarboxylates are presented in Table 1 and 2,6-pyridinedicarboxylates are presented in Table 2. The spectral assignments were done on the basis of the literature data (McCann and Laane, 2008; Karabacak et al., 2015) and calculated IR wave numbers of studied compounds. Theoretical spectra for acids and lithium, sodium, potassium salts were calculated by DFT/B3LYP method on 6-311++G\*\* basis. Calculated normal vibrations were characterized by computer animation. A good correlation between experimental and theoretical IR and Raman spectra was noted. The correlation coefficients for the IR spectra are higher than 0.990. Normal vibrations of the aromatic ring were given by Varsanyi (1973). The changes of intensities and wave numbers of the bands of the aromatic system in the case of salts were discussed, in comparison with the free ligands. Substitution of the metal ion in the two groups of carboxylic acids results in the disappearance of the characteristic vibration of the carboxyl group, such as v(C=O) in 2,3-PDA present at 1707, 1622 cm<sup>-1</sup> in the IR<sub>KBr</sub> spectrum, 1706 cm<sup>-1</sup> in the IR<sub>ATR</sub> spectrum, 1698 cm<sup>-1</sup> in Raman, in the 2,6-PDA acid present at 1701 cm<sup>-1</sup> in IR<sub>KBr</sub>, 1693 and 1634 cm<sup>-1</sup> in IR<sub>ATR</sub> and 1644 cm<sup>-1</sup> in Raman; v(C=O) in 2,3-PDA present at 1307 cm<sup>-1</sup> in IR<sub>KBr</sub>, 1307 cm<sup>-1</sup> in IR<sub>ATR</sub>, 1309 cm<sup>-1</sup> in

Raman, in 2,6-PDA present at  $1328 \text{ cm}^{-1}$  in IR<sub>KBr</sub>,  $1331 \text{ cm}^{-1}$  in IR<sub>ATR</sub> and  $1328 \text{ cm}^{-1}$  in Raman. Vibration bands of the hydroxyl group i.e.  $\nu(\text{OH})$ ,  $\beta(\text{OH})$  and  $\gamma(\text{OH})$  disappear as well. The disappearance of the bands characteristic of the carboxyl group indicates that the two carboxyl groups are being substituted by the metal ion. In the spectra of salts there appear bands assigned to vibrations of the carboxylate anion (the metal to ligand ratio was 2:1). In the alkali metal salts with 2,3-PDA these new vibrations give characteristic wide and intense two bands responsible for the  $\nu_{\text{as}}(\text{COO}^-)$  ( $1626$ – $1590$  and  $1579$ – $1575 \text{ cm}^{-1}$  in IR<sub>KBr</sub> spectra,  $1623$ – $1587$  and  $1573$ – $1562 \text{ cm}^{-1}$  in IR<sub>ATR</sub>,  $1633$ – $1623$  and  $1581$ – $1571 \text{ cm}^{-1}$  Raman spectra) and  $\nu_{\text{sym}}(\text{COO}^-)$  ( $1408$ – $1382 \text{ cm}^{-1}$  in IR<sub>KBr</sub> spectra,  $1403$ – $1372 \text{ cm}^{-1}$  in IR<sub>ATR</sub>,  $1409$ – $1386 \text{ cm}^{-1}$  in Raman spectra) stretching of the carboxylic anion. The bands assigned to the symmetric in-plane deformation of the carboxylic anion ( $\beta_{\text{sym}}$ :  $843$ – $830 \text{ cm}^{-1}$  IR<sub>KBr</sub> spectra,  $843$ – $823 \text{ cm}^{-1}$  IR<sub>ATR</sub>,  $846$ – $823 \text{ cm}^{-1}$  Raman spectra) and asymmetric in-plane deformation of the carboxylic anion ( $\beta_{\text{as}}$ , observed only in the case of lithium salt,  $497 \text{ IR}_{\text{KBr}}$ ). Bands derived from the carboxylate anion vibration in the spectra of the alkali metal salt of the 2,6-PDA occur at somewhat higher wave numbers than it is the case of the spectra of 2,3-PDA salts. In the alkali metal salts with 2,6-PDA these vibrations gave characteristic wide and intense two bands responsible for the  $\nu_{\text{as}}(\text{COO}^-)$  ( $1656$ – $1646$  and  $1612$ – $1609 \text{ cm}^{-1}$  in IR<sub>KBr</sub> spectra,  $1658$ – $1631$  and  $1614$ – $1669 \text{ cm}^{-1}$  in IR<sub>ATR</sub>,  $1665$ – $1636$  and  $1619 \text{ cm}^{-1}$  in Raman spectra) and  $\nu_{\text{sym}}(\text{COO}^-)$  ( $1384$ – $1378 \text{ cm}^{-1}$  in IR<sub>KBr</sub> spectra,  $1385$ – $1365 \text{ cm}^{-1}$  in IR<sub>ATR</sub>,  $1397$ – $1386 \text{ cm}^{-1}$  in Raman spectra) stretching of the carboxylic anion. The bands assigned to the symmetric in-plane deformation of the carboxylic anion,  $\beta_{\text{sym}}$  occur at  $827$ – $816 \text{ cm}^{-1}$  in IR<sub>KBr</sub>,  $826$ – $813 \text{ cm}^{-1}$  in IR<sub>ATR</sub>,  $826$ – $815 \text{ cm}^{-1}$  in Raman. Asymmetric in-plane deformation of the carboxylic anion was not observed in the 2,6-PDA salts.

The bands derived from aromatic ring vibrations of the studied acids and their salts with alkali metals are present in the entire spectral range. As compared to the spectra of acids, in the spectra of the salts a decrease in the wave numbers can be seen and the intensity of vibrations of the aromatic system is reduced. A number of bands present in the acid spectra disappear in the salts upon the metal ion substitution at the carboxyl group and as well some additional bands emerge that aren't present in the spectra of the ligands. Based on the comparison of the wave numbers and intensities of the aromatic ring vibration bands (vibration of C–C and C–H bonds in the aromatic ring) in the ligand and salts, some conclusions can be drawn on the influence of metal on a disturbance or stabilization of the aromatic ring. The disturbance of this system is indicated by the reduction in the number and intensity of the bands derived from the aromatic system vibrations and/or their shift toward lower wave numbers in the IR and Raman spectra of the complexes compared to the spectrum of a given acid; this is due to the reduction in the force constants and polarization of C–C and C–H bonds in the ring. It was observed that in the IR and Raman spectra more bands present on the ligand disappear in the case of 2,3-PDA salts than it is in the case of 2,6-PDA salts. In addition, salts of 2,6-PDA reveal more new ligand bands than 2,3-PDA salts. The wave numbers of some bands present in the spectra of the salts tested decrease in the series Li → Na → K → Rb → Cs. These changes are not regular as it is observed for the spectra of alkali metal salts with monocarboxy-pyridinecarboxylic acids.

**Table 2** Wave numbers ( $\text{cm}^{-1}$ ), intensities and assignments of bands occurring in the IR (KBr, ATR and DFT) and Raman spectra of 2,6-pyridinedicarboxylic acid and lithium, sodium, potassium, rubidium and cesium 2,6-pyridinedicarboxylates.

### 3.2. NMR spectra

Chemical shifts of the signals coming from protons in the  $^1H$  NMR spectra of 2,3- and 2,6-PDA alkali metal salts take lower values than the corresponding ones for acids (Tables 3 and 4). An aromatic pyridine ring is disturbed, resulting in a change in the electron density around the protons of the aromatic ring. The values for the chemical shifts of aromatic protons labeled H3, H4 and H5 in the spectra of acid and its salts 2,6-PDA overlap to give a single band in the spectrum. For 2,3-PDA acid and its salts the three aromatic protons give its spectral image of three clearly separated signals. Decreases in proton chemical shifts for H4 and H5 in 2,3-PDA acid salts are small, and the decreases in proton chemical shifts for H3 are much larger and similar in size as those in 2,6-PDA salts.

The decisive factor influencing the electron charge distribution on the pyridine ring of 2,3-PDA and 2,6-PDA is the distribution of carboxyl groups linked to the ring. In the case of dipicolinic acid, the carboxyl groups are arranged symmetrically with respect to the nitrogen atom, with the consequence that the electronic charge around the carbon atoms is arranged symmetrically in the molecule. This can be observed as the equal values of the chemical shifts of carbons C2=C6 and C3=C5 in the  $^{13}C$  NMR spectrum. In the case of 2,3-PDA, the carboxyl groups are asymmetrically attached to the aromatic ring, thereby the values for the chemical shifts of the carbons are asymmetrically distributed. Substitution of the carboxyl groups with an alkali metal atom induces the changes in the electronic charge distribution (implying the changes in the chemical shifts of the carbon atoms in the observed  $^{13}C$  NMR spectra). Changes in the values of the chemical shifts for the carbon atoms in the spectra of 2,6-PDA salts occur in a symmetrical manner, i.e. the same increase in the chemical shifts of carbon C2 and C6, and the same decrease in chemical shifts for carbons C3 and C5 can be observed. In the case of 2,3-PDA salts, changes in the chemical shifts of the carbons (indicating the redistribution of the electronic charge in the molecules) are not symmetrical. In the series of salts of both acids the same direction of changes in chemical shifts is observed, i.e. an increase in the value of the signals for the carbon atoms C2 and C6 (decrease in electron density) and a decline in the value of the signals for C4 and C5 (increase in electron density) are found. Otherwise, for the C3 carbon atom of the 2,3-PDA salts an increase in chemical shifts relative to acid can be seen, whereas for the 2,6-PDA salts chemical shift values decrease. In conclusion, the electronic charge of the pyridine ring in the case of 2,6-PDA is distributed more evenly than in 2,3-PDA. Alkali metals perturb the electronic system to much higher degree, if the alkali metal atom is substituted to the carboxyl groups of 2,3-PDA than to those of 2,6-PDA.

### 3.3. Thermogravimetric study

Thermogravimetric studies of the 2,3- and 2,6-pyridinecarboxylate alkali metal salts (Tables 5 and 6) showed that the degrees of hydration of the 2,6-PDA alkali metal salts were very similar in the series (Li—Na—K—Rb—Cs). In the case of 2,3-PDA salts, the degree of hydration of each salt was also similar. The salts prior to the studies were dried for 24 h at 70 °C. Dehydration occurs in a

single step for the salts tested (all hydrated salts). For the 2,6-PDA salts the dehydration process begins at 100 °C. Sodium and potassium salts of 2,6-PDA loose water in the temperature range of 100–210 °C, and all other salts in the range of 100–150 °C. The process for the dehydration of the 2,3-PDA salts starts at slightly higher temperatures (above 130 °C). After dehydration, in subsequent steps the process of decomposition of the tested compounds occurs. Both acids are degraded completely in a one-step process of decomposition at about 250 °C. Studies on the decomposition of salts in the range of 70–890 °C showed that the decomposition proceeds via formation of alkali metal carbonates and in a later step in the case of certain salts, to alkali metal oxides. In the first step in a temperature range from ca 370 to 500 °C beside carbonates some residues of organic carbon are found as well that are formed during the decomposition of the aromatic ring. This can be seen as

a pitch curve on TG and DTA graphs (Fig. 3). In a further step of the decomposition process the organic carbon residues are oxidized to carbon dioxide and a product in the form of carbonate is formed. In the case of sodium salts the produced carbonates are stable in a range of temperatures, while for the other salts a decomposition of carbonates to the oxides of alkali metals occurs. Comparing the curves illustrating the thermal decomposition of the alkali metal salts of the two studied acids (Fig. 3) one can observe that salts of 2,6-PDA are dehydrated at a slightly lower temperature than the salts of 2,3-PDA. In contrast, the decomposition of the aromatic ring occurs at a slightly lower temperature in the case of 2,3-PDA salts than for those of 2,6-PDA. Based on the decomposition curve, it can be concluded that the 2,3-pyridinedicarboxylates are thermally less stable than the 2,6-pyridinedicarboxylates of the alkali metals.

**Figure 3** TG/DTA curves of 2,3-pyridinedicarboxylic acid (A) and sodium salts (B), 2,6-pyridinedicarboxylic acid (C) and sodium salts (D).

#### 4. Conclusions

It was observed that in the IR and Raman spectra of 2,3-PDA alkali metal salts there disappear more bands that are initially present in the ligand than in the case of 2,6-PDA salts. In addition, in the salts of 2,6-PDA more new bands appear than in the case of 2,3-PDA salts, as compared to the respective ligand.

Changes in the spectra of the alkali metal salt of the acid with respect to the acid spectra are related to the effects of metal on the electron charge distribution of the aromatic ring of the ligand. The alkali metals destabilize the electronic system, and the effect is greater for 2,3-pyridinecarboxylates. In the case of 2,6-PDA acid molecules electron charge distribution in the aromatic ring is symmetrical with respect to the nitrogen atom, due to the symmetrical position of the carboxyl groups, what is indicated by chemical shift values in  $^1\text{H}$  NMR and  $^{13}\text{C}$  NMR spectra. Alkali metal substitution in the carboxyl group of this acid causes changes in the distribution of electron charge (seen as changes in chemical shifts), and the symmetry of the charge distribution in the aromatic ring is retained with respect to the heteroatom. When the carboxylic groups take an asymmetric position relative

to the heteroatom in the 2,3-PDA ring, the asymmetric distribution of electron charge is observed. An alkali metal atom substitution in the carboxyl group induces an increase of an asymmetric charge distribution in the aromatic ring – a perturbation of the charge distribution increases in the tested series of salts in the order  $\text{Li} \rightarrow \text{Na} \rightarrow \text{K} \rightarrow \text{Rb} \rightarrow \text{Cs}$ . Based on the decomposition curve it can be concluded that the 2,3-pyridinedicarboxylates of alkali metals are thermally less stable compounds than the 2,6-pyridinedicarboxylates of the alkali metals.
