Azo-imine ligand; Complex; Thermal; Catalysis

Abstract This work explains the synthesis of a new azo-Schiff base compound, derived from condensation between N-ethylcarbazole-3-carbaldehyde and 1,3-diaminopropane, followed by azo coupling reaction with the diazonium salt of 2-amino-4-methyl phenol. The newly synthesized azo-Schiff base was further reacted with the acetate salts of Copper, Cobalt and Nickel to give three coordination compounds. All synthesized compounds have been characterized through spectral analysis. The coordination compounds have been examined for their thermal and catalytic features. Good and moderate yields were obtained for the oxidation of styrene and cyclohexene. Thermal features of the ligand and its complexes have been explained and the results obtained have supported the proposed structures.

1. Introduction

During the past two decades, considerable attention has been paid to the chemistry of Schiff bases and their metal complexes. Schiff bases are a class of important compounds in medicinal and pharmaceutical field. So far, various azo containing Schiff bases have been synthesized, characterized and examined for their different features such as antimicrobial, antifungal, electronic, and thermal (Ghasemian et al., 2014a, b; Eren et al., 2014; Bal et al., 2014a,b; Menati et al., 2013; Kose et al., 2013; Shaghaghi, 2014).

In addition to above features, the catalysis of alkene oxidation by soluble transition metal complexes is of great interest in both biomimetic and synthetic chemistry (Heshmatpour et al., 2012; Islam et al., 2013; Chen et al., 2013). Because the oxidation reactions are carried out in elevated temperatures, it has become important to synthesize thermally stable Schiff base complexes as catalysts. In the literature various Schiff bases had been tested as catalysts toward different oxidation reactions of saturated or unsaturated organic compounds (Huang et al., 2013; Silva et al., 2013; Netalkar et al., 2014). Some azo containing Schiff base complexes had also been used as catalysts in many organic reactions such as oxidations or...
reductions on many chemical compounds (Mirkhani et al., 2004; Ispiri, 2009; Ozdemir, 2014; Urusu et al., 2012; Pardhi et al., 2010; Islam et al., 2010; Bansod and Aswar, 2007). With this work, we have synthesized a new, carbazole derived azomethine Schiff base and its Cu (II), Co (II) and Ni (II) complexes. The ligand and the coordination compounds were fully characterized and examined for their thermal and catalytic features.

2. Experimental

9-Ethylcarbazole, Phosphorus (V) oxychloride, 1,3-diaminopropane, 2-amino-4-methylphenol, acetate salts of Copper (II), Cobalt (II) and Nickel (II) were purchased from Sigma Aldrich. Nuclear Magnetic Resonance spectra were recorded on a Bruker AV 300 MHz spectrometer in the solvent CDCl3. Infrared spectra were obtained using KBr discs on a Shimadzu 8300 FTIR spectrophotometer. The oxidation products were analysed with a gas chromatograph (Shimadzu, GC-14B) equipped with a SAB-5 capillary column and a flame ionization detector. MS spectrometry was performed with a LC/MS APCI AGILENT 1100 MSD spectrophotometer. The thermal analyses were performed on a LECO CHNS 932 elemental analyser and the metal analyses were carried out on an Afi Unicam 929 Model AA Spectrometer in solutions prepared by decomposing the compounds in aqua regia and subsequently digesting them in conc. HCl. The elemental analyses of synthesized ligand and its metal complexes were carried out on a Perkin-Elmer Thermogravimetric Analyser TG/DTA 6300 instrument under nitrogen atmosphere between the temperature range 30 °C and 988 °C at a heating rate of 10 °C/min. Magnetic measurements were carried out by the Gouy method using Hg[Co(SCN)4] as calibrant. Molar conductances of the Schiff base ligands and their transition metal complexes were determined in MeOH (ca.10⁻³ M) at room temperature using a Jenway Model 4070 conductivity meter.

2.1. Synthesis of the ligand

Formylation of 9-ethylcarbazole was done by using Vilsmeier formylating agent DMF and POCl3 (Grigoras and Antonoua, 2005; Yoon et al., 2007; Bal and Bal, 2014). The monoaldehyde was separated by flash chromatography with ethyl acetate/hexane (1:10) as eluent. N-Ethylcarbazole-3-carbaldehyde was then reacted with 1,3-diaminopropane to give the imine compound; (Z,Z)-N,N’-bis[9-ethyl-9H-carbazol-3-yl)methylene]propane-1,3-diamine, which was previously synthesized and characterized by us (Bal and Bal, 2014). Finally, our ligand was synthesized through azo coupling reaction (Eren et al., 2014; Bal et al., 2014a,b) between diazonium salt of 2-amino-4-methylphenol and (Z,Z)-N,N’-bis[9-ethyl-9H-carbazol-3-yl)methylene]propane-1,3-diamine. Synthesis scheme can be seen in Fig. 1.

Chemical formula: C₂₉H₃₄N₄O₄. Yield: 70%, m.p.: 185–187 °C, Elemental Analysis found% (calculated%): C 75.21 (74.98) H 6.1(5.89) N 14.91(14.88). UV–Vis (ethanol) (λmax, nm): 265, 358, 448. FT-IR (KBr, cm⁻¹): 3390 (brd) (ArOH), 2971 (w), 2847 (w), 2919 (w), 1598 (w) (Ar–H, C–H); 742(s) (Ar=H), 1615(s) (CH=CH), 1471(s) (N=CH). Mass spectrum (LC/MS APCI): m/z 737.4 [M–CH₃]+. ¹H NMR (300 MHz,CDCl₃): 8.1 (H-5, H-5'), s), 7.91 (H-2, H-2', d, J = 8.4 Hz), 4.41 (H-14, H-14', q, J = 7.2), 1.47 (H-15, H-15', t, J = 7.2), 8.6 (H-16,H-16', s), 3.84 (H-17'H-19, t, J = 6.8), 2.26 (H-18, pentet, J = 6.8), 7.2 (H-21, H-21', s), 7.0 (H-23, H-23', d, J = 7 Hz), 6.9 (H-24, H-24', d, J = 8.1 Hz), 2.1 (3H-26, 3H-26', s). 13C NMR (400 MHz,CDCl₃): 126.04 (C-1, C-1'), 125.9 (C-2, C-2'), 127.6 (C-3, C-3'), 123.1 (C-4, C-4'), 120.7 (C-5, C-5'), 119.4 (C-6, C-6'), 108.5 (C-7, C-7'), 108.7 (C-8, C-8'), 141.5 (C-10), 127.2 (C-11, C-11'), 124.0 (C-12, C-12'), 140.5 (C-13, C-13'), 37.7 (C-14, C-14'), 13.8 (C-15, C-15'), 162.06 (C-16, C-16'), 59.5 (C-17&C-19), 32.3 (C-18), 135.9 (C-20, C-20'), 120.34 (C-21, C-21'), 136.7 (C-22, C-22'), 120.84 (C-23, C-23'), 120.92 (C-24, C-24'), 150.0 (C-25, C-25'), 29.7 (C-26, C-26'). A_M (Ω⁻¹ cm⁻² mol⁻¹): 7.

2.2. Synthesis of complex compounds

Acetate salts (1 mmol) of Cu(II), Co(II) and Ni(II) were mixed with ethanol solution of our ligand (1 mmol). The resulting mixtures were left refluxing overnight. Complex compounds were crystallized from ethanol.

2.2.1. Copper(II) complex of L

Cu(LH₂O₂)(AcO)₂ Complex: (C₅₁H₅₄CuN₈O₈), yield: 62%, m.p.: 220–223 °C, Elemental Analysis found% (calculated%): C 63.77(63.11), H 5.32(5.61), N 11.53(11.55), Cu 6.70(6.55). UV–Vis (ethanol) (λmax, nm): 297, 347, 390, 510. FT-IR (KBr, cm⁻¹): 3600(brd), 3364(brd), 3267(brd) (OH, H₂O), 2979(m), 2875(m) (Ar=H, CH), 1552 (s) (CH=CH), 1590(s) (V₃(υ CO)), 1417(V₂, CO), 1498(s) (N=CH), 470(s) (M=CH), 625(s) (M=O). Mass spectrum (LC/MS APCI): m/z 971.3 [M + H]+. A_M (Ω⁻¹ cm⁻² mol⁻¹): 19.9. μ_eff (B.M.): 1.92.

2.2.2. Cobalt(II) complex of L

Co(LH₂O₂)(AcO)₂ Complex: (C₅₁H₅₄CoN₈O₈), yield: 70%, m.p.: 215–217 °C, Elemental Analysis found% (calculated%): C 63.98(63.41), H 5.91(5.63), N 11.55(11.60), Co 6.34(6.10). UV–Vis (ethanol) (λmax, nm): 285, 351, 516. FT-IR (KBr, cm⁻¹): 3361(brd) (OH, H₂O), 2973(m), 2855(m) (Ar=H, CH), 1554 (s) (CH=CH), 1591 (s) (V₃(υ CO)), 1410(V₂, CO), 1495(s) (N=CH), 472(s) (M=CH), 614(s) (M=O). Mass spectrum (LC/MS APCI): m/z 965.2 [M++]. A_M (Ω⁻¹ cm⁻² mol⁻¹): 12.7. μ_eff (B.M.): 4.91.

2.2.3. Nickel(II) complex of L

Ni(LH₂O₂)(AcO)₂ Complex: (C₅₁H₅₄NiN₈O₈), yield: 62%, m.p.: 217–218 °C, Elemental Analysis found% (calculated%): C 63.81(63.43), H 6.11(5.64), N 11.49(11.60), Ni 6.10(6.08). UV–Vis (ethanol) (λmax, nm): 292, 345, 512. FT-IR (KBr, cm⁻¹): 3400(brd) (OH, H₂O), 2922(m), 2844(m) (Ar=H, CH), 1557 (s) (CH=CH), 1590 (s) (V₃(υ CO)), 1416(V₂, CO), 1499(s) (M=CH), 455(s) (M=CH), 617(s) (M=O). Mass spectrum (LC/MS APCI): m/z 965.0 [M+]. A_M (Ω⁻¹ cm⁻² mol⁻¹): 15.3. μ_eff (B.M.): 3.11.

2.3. Oxidation procedure

A mixture of 1.0×10⁻³ mol catalyst, 20 ml solvent (CH₃CN) and 10 mmol cyclohexene/styrene was stirred under nitrogen atmosphere in a 50 ml round-bottom flask. Then 20 mmol hydrogen peroxide (30% in water) was added dropwise. The
resulting mixture was vigorously stirred for 8 h at 60 °C. After filtration and washing with solvent, the filtrate was concentrated and then subjected to GC analysis. The yields were recorded as the GC yield based on the starting styrene or cyclohexene. The identity of the oxidation products was confirmed by GC–MS. A blank reaction was also carried out without any catalyst for both oxidation reactions.

3. Results and discussion

3.1. Spectral analysis

$^1$H NMR spectrum of our ligand (Fig. 2) showed the ethyl group protons on the carbazole units at 4.41 ppm (2H-14) as
quartet (\(J = 7.2 \text{ Hz}\)) and at 1.47 ppm (3H-15) as triplet (\(J = 7.2 \text{ Hz}\)). The protons on the propane moiety were appeared at \(\delta 3.84 (2H-17 \& 2H-19)\) as triplet (\(J = 6.8 \text{ Hz}\)) and at \(\delta 2.26 (2H-18)\) as pentet (\(J = 6.8 \text{ Hz}\)). The methyl protons on the propane moiety appeared at \(\delta 2.1 \text{ ppm}\) as singlet. The two phenolic protons appeared at \(\delta 2.1 \text{ ppm}\) and the hydroxyl protons were at around \(\delta 10 \text{ ppm}\) (Kose et al., 2013). We had identified the proton signals belonging to the carbazole unit previously (Bal and Bal, 2014). In the proton NMR of our newly synthesized ligand, we were able to see the hydrogens of 4 and 4’ at 8.6 ppm as singlet overlapping with the imine protons. The signal seen as a singlet at 8.1 ppm belongs to H-5 and H-5’ on carbazoles and the doublet observed at \(\delta 7.91 (J = 8.4 \text{ Hz})\) was attributed to H-2 and H-2’. The other carbazole ring protons were seen between 7.3 ppm and 7.7 ppm. Considering the phenolic rings in our compound, we have seen the two isolated hydrogens of 21 at 7.2 as a singlet and the hydrogens of 23 and 24 were seen as doublets at 7 ppm and 6.9 ppm respectively. The methyl carbons para to the hydroxyls were seen at 29.7 (Gozel et al., 2014). The ethyl groups attached to Nitrogen on the carbazole units were at 37.7 ppm (C-14, C-14’) and at 13.9 (C-15, C-15’). The carbons belonging to 1,3-diaminopropane between the two carbazoles were observed at \(\delta 59.5 (C-17, C-19)\); \(\delta 32.3 (C-18)\). The IR spectra of all the complexes showed a considerable red shift in their imine stretching frequencies compared to that of the ligand itself, which proves that the complexation took place on the imine Nitrogens. Also, it is a common knowledge that the imine Nitrogens are always more likely to undergo complexation in the presence with transition metals. Although it is changeable, depending on the metal (Shindo and Brown, 1965) and the structures of the ligands (e.g. containing electronegative atoms) (Cabaniss and McVey, 1995), it is generally known that the bands between 1380 and 1600 cm\(^{-1}\) are attributed to the symmetric and anti-symmetric stretching modes of carboxylate groups respectively (Finnie et al., 1998). The UV spectra of all complexes showed symmetric and asymmetric carboxylate stretchings, proving the acetate coordinations to the metals, and the difference between the splitting of carboxylate stretching bands (\(\Delta = V_{\text{as}} - V_{\text{sym}}\)) in our complexes were found to be between 173 and 181 as shown below. These results prove the undentate pattern of carboxylate coordinations (Finnie et al., 1998).

UV spectra of the coordination compounds gave d-d\(^*\) transitions between 510 nm and 516 nm. The other transitions were between 265 nm and 448 nm. Apart from their parent ions, mass spectra of the synthesized coordination compounds showed two fragments, one of which belongs to carbazole units with the imine groups (2\(\times\)C\(_9\)H\(_{12}\)N\(_2\)) and the other fragment belongs to the two phenolic groups with azo groups attached to them (2\(\times\)C\(_7\)H\(_7\)N\(_2\)O) at 440 m/z and at 270 m/z.
respectively. The magnetic susceptibilities of all complexes were measured at room temperature. The Copper (II) complex exhibits 1.92 B.M. value, suggesting it has an octahedral geometry (El-Seıdy, 2015). The Cobalt complex, also, comes closer to an octahedral structure with a B.M. value of 4.91 (Shennar et al., 2015). Again, the typical octahedral Nickel complex showed its B.M. value as 3.11 (Shennar et al., 2015). Molar conductivities of the ligand and its coordination compounds were between 7 and 19.9 Ω⁻¹ cm² mol⁻¹, which proves their nonelectrolyte features (Tumer et al., 1999).

3.2. Thermal analysis

TG traces of the synthesized compounds provided additional information regarding their thermal stabilities and thermal degradation behaviors (Fig. 4). Examination of the thermogram of our ligand shows continuous weight losses, which can be divided somewhat distorted intervals as shown in Table 1. The biggest weight loss was observed for the loss of two carbazole units with a percentage of 47.9 (calc. 47.3). The residual part, however, was around 12.3% (calc. 12.7%) and this percentage can be attributed for the loss of C₃H₆N₂ unit that is the 1,3-diaminopropane unit in the middle of the two carbazoles. TG graphic of the Copper complex of the ligand reveals the loss of two ethyl groups on carbazoles between 100 and 180 °C. The second loss between 220 and 300 °C was assigned to two molecule azo containing phenolic groups with loss of 28.6%. Above 300 °C, the biggest weight loss was recorded as 47.1% (Calc.46.9%), corresponding to two carbazole units, diaminopropane bridge (C₃H₆N₂) and the water molecules in the lattice. Cobalt coordination compound shows two degradation steps, the biggest mass loss happens between 110 °C and 700 °C with a percentage of 75 (Calc. 75.6%) which corresponds to the distinct parts of the whole molecule. The residual parts of all complexes of our ligand gave the masses of the two acetate units and the Copper and Cobalt metallic losses were seen in the residual parts of CuL(H₂O)₂(AcO)₂ and CoL(H₂O)₂(AcO)₂; however, the Nickel metallic loss was found with the losses of two ethyl groups and two water molecules in the first half of the thermal graphic of NiL(H₂O)₂(AcO)₂, the second half of which gave the biggest loss with a mass loss of 70.8% (Calc. 71.1).

3.3. Catalytic activity

Among the complex compounds, Copper (II) coordination compound showed better catalytic activity compared to the other coordination compounds. Both styrene and cyclohexene conversion percentages were 75.3% and 70.2% respectively and the styrene oxide selectivity was recorded as 22.2% while the cyclohexene oxide selectivity was 25.3%. Cobalt complex can be recorded as the second best catalyst in these oxidation reactions with 61.3% styrene and 59.7% cyclohexene conversion. The Nickel (II) complex, however, gave poorer results in both styrene oxidation and cyclohexene oxidation reactions. Catalytic activity results can be seen in Table 2 and Fig. 5 shows the possible oxidation reaction schemes.

Reaction conditions: Alkene (10 mmol), H₂O₂ (20 mmol), catalyst (1 mmol), CH₃CN (20 mL) at 60 °C.

Others for styrene oxidation: Benzoic acid, Phenylacetaldehyde, 1-phenylethanol-1,2-diol.

Others for cyclohexene oxidation: 2-Cyclohexene-1-one, 2-cyclohexene-1-hydroperoxide.
4. Conclusion

With this work we have synthesized and characterized a new carbazole derived, azo containing Schiff base ligand and its Copper (II), Cobalt (II) and Nickel (II) complexes. Newly synthesized compounds were examined for their thermal and catalytic activity features. Thermal analysis supported the spectral analyses and is in agreement with the proposed structures of the ligand and its complexes. Catalytic activity results showed that in the oxidation reactions of styrene and cyclohexene Copper (II) complex was the most effective complex. This may be related to its thermal stability since the Copper complex was more temperature resistant than the other coordination compounds according to the thermal graphics.
