were significantly larger than those of the volunteers. Although there was a positive correlation between body mass index and visceral fat area (r=0.86, p<0.01), the ratio of visceral fat area to body mass index was also higher in the hospitalized patients (3.24 ± 1.40 vs 2.11 ± 0.61, p<0.01). Correlations of age to body mass index (r=0.09, p=0.44) and visceral fat area (r=-0.16, p=0.14) were not significant, however, the ratio of visceral fat area to body mass index had a weak correlation to age (r=-0.24, p=0.03).

**Conclusion:** Hospitalized patients in the cardiology ward had larger visceral fat. Further investigation is needed to demonstrate clinical usefulness of this novel technique.

The Protective Effect of PEP-1-CAT Fusion Protein Preconditioning on Myocardial Ischemia-reperfusion Injury in Rats

Yongjun Zhang, Xiaoluan Wang

The Sixth People’s Hospital Affiliated to Shanghai Jiaotong University, Shanghai, China

**Background:** Myocardial infarction is a leading cause of death and disability, with a direct correlation between infarct size and prognosis. Early reperfusion is an absolute prerequisite for the survival of ischemic myocardium. However, reperfusion itself may lead to accelerated and additional myocardial injury beyond that generated by ischemia alone. Oxygen free radical theory is an important mechanism of ischemia-reperfusion injury. Hydroxyl, which has high high toxicity, can be removed by CAT in the stage of reperfusion, endogenous CAT is relatively scanty. CAT does not readily penetrate through membranes but CAT can penetrate through cell TCTAP A-208 membranes by PEP-1. And PEP-1-CAT has biological activity.

**Methods:** A total of 40 male rats were divided into 5 groups at random: Sham-operated group, ischemia-reperfusion group (I/R group), PEP-1-CAT-treated group (group 1, group 2, group 3). 1ml NS were injected via caudal vein in sham-operated group and ischemia-reperfusion group, 100ug, 300ug and 500ug PEP-1-CAT were administered via caudal vein respectively. 7 hours later, the left main coronary artery was occluded for 30 minutes followed by a 24-hour reperfusion in anesthetized rats, at the end of reperfusion, hemodynamics were measured. Infarct size were measured by TTC staining. LDH, CK in blood serum and MDA in myocardium were measured according to the manufacturer’s protocol. The myocardial cell apoptosis was determined with TUNEL (TdT-mediated dUTP Nick-End Labeling) method. Immunofluorescent method was used to detect the expression changes of bcl-2 and bax in rat myocardium of left ventricle.

**Results:** Compared with I/R group, PEP-1-CAT-treated groups, LVEDP and dp/dtmax were increased (p<0.01), LVEDP were decreased (p<0.01). Cardiac infarct areas appeared in each group, but the infarct size in PEP-1-CAT fusion protein groups were significantly lower than I/R group (p<0.05 or p<0.01). The myocardial MDA content in the stage of reperfusion was significantly lower in PEP-1-CAT-treated groups compared with I/R group (p<0.01). DAPI marked nucleus demonstrated blue fluorescence when excited under UV light, whereas the expression of Bcl-2 and Bax protein in the cytoplasm as well as nucleus membrane demonstrated brilliant green fluorescence, some of which were merged especially in bcl-2. Compared with I/R group, the drug group markedly decreased the expression of Bax (p<0.01), the ratio of Bax to Bcl-2 was decent incidentally.

**Conclusion:** PEP-1-CAT preconditioning has protective effect on ischemia-reperfusion injury, this may be related with anti-oxidant and anti-apoptosis effect.

Three-year Cumulative Incidence of New-onset Diabetes: Are There Differences Between Atorvastatin and Simvastatin?

Sung guy Yoon1, Seung-Woon Rha2, Byoung Geol Choi2, Se Yeon Shin3, Seung-Woon Bha4, Byoung Geol Choi2, Choel Ung Choi5, Cheol Ung Choi5, Chang Gyu Park2, Hong Euy Lim2, Hong Seog Seo2, Dong Joo Oh2, Ji Bak Kim2, Sung Il Im2, Sung-Hye Park2, Ji Young Lim2, Jin Won Kim2, Eung Ja Kim5, Chang Gyu Park2, Hong Seog Seo2, Dong Joo Oh5, Soochunhyang University Cheonan Hospital, Cheonan, Korea (Republic of), 1Soochunhyang University Hospital, Seongnam, Korea (Republic of), 2Korea University Guro Hospital, Seoul, Korea (Republic of)

**Background:** Chronic statin administration may be associated with modestly increased risk of new-onset type 2 diabetes mellitus (T2DM). However, there were no data whether there are different in increased risk of new-onset type 2 diabetes mellitus (T2DM). However, there were no significant difference at baseline. There was no significant difference in cumulative incidence of new-onset T2DM up to 36 months (Figure).

**Conclusion:** In our study, the cumulative incidence of new-onset T2DM up to 36 months were not different between chronic simvastatin and atorvastatin use.

Impact of Hemodialysis in Critical Limb Ischemia Patients with Infra-popliteal Arterial Lesion on Clinical Outcomes Following Percutaneous Transluminal Angioplasty

Sang-Ho Park1, Seung-Woon Rha2, Byoung Geol Choi2, Won-Yong Shin3, Se-Yeon Cheo4, Youngjee Park5, Akkala Raghavender Goud6, Hu Li7, Sunki Lee7, Ji-Bak Kim8, Sung Il Im2, Jin Oh Na7, Cheol Ung Choi5, Hong Euy Lim2, Jin Won Kim5, Eung Ja Kim5, Chang Gyu Park2, Hong Seog Seo2, Dong Joo Oh5, Soochunhyang University Cheonan Hospital, Cheonan, Korea (Republic of), 2Korea University Guro Hospital, Seoul, Korea (Republic of)

**Background:** In general, it has been known that hemodialysis was associated with vascular calcification and adverse clinical outcomes following endovascular intervention (EVT). Although the success rate of infra-popliteal arterial lesion causing critical limb ischemia (CLI) is becoming very high; however, the impact of hemodialysis on the major clinical outcomes following successful EVT is not clarified yet.

**Methods:** This study consisted of 115 consecutive CLI patients (pts) with infra-popliteal arterial lesion underwent EVT from September 2006 to September 2010. Procedural success was defined once the balloon angioplasty outcome is not optimal, mainly by self-expanding nitinol stents. 1-year clinical outcomes of hemodialysis group (n=89 pts) were compared with those of non-hemodialysis group (n=26 pts) up to 12 months.

**Results:** The baseline clinical characteristics were similar between the two groups except that the combined femoral arterial lesion (61.5% vs. 38.2%) was more frequent in the hemodialysis group. 1-year repeat revascularization such as TLR, TER was similar between the two groups. However, the incidence of unknown origin death (16.7% vs. 0%, p=0.006) and ostectomy (27.8% vs. 8.1%, p=0.036) was higher in the hemodialysis group (table).

**Conclusion:** In our study, at 1 year, despite of similar incidence of repeat revascularization, the incidence of non-cardiac death and surgical intervention (ostectomy, amputation, debridement) was higher in the hemodialysis group. Thus, CLI pts on hemodialysis should be managed by more intensive care.
