## Note

# A Note on Convergence of Quadratic Interpolatory Splines 

M. Shrivastava<br>Department of Mathematics, R. D. University, Jabalpur, India Communicated by Oved Shisha<br>Received June 27, 1986

Marsden [1, 2] has obtained some error estimates concerning quadratic splines interpolating given functional values at the midpoints between the knots. In this note we point out that it is possible to improve three such estimates. Adopting the definitions and notation used in Marsden [1], we shall prove the following

Theorem. Let $y$ and $y^{\prime}$ be continuous and periodic functions. Then (i) $\left\|e_{i}^{\prime}\right\| \leqslant(5 / 2) w\left(y^{\prime}, p / 2\right)$; (ii) $\left\|e^{\prime}\right\| \leqslant 4 w^{\prime}\left(y^{\prime}, p / 2\right)$; (iii) $\|e\| \leqslant 2 p w\left(y^{\prime}, p / 2\right)$.

Proof of the Theorem. A little calculation shows that the following equalities hold.

$$
\begin{align*}
& p_{i}^{2} s(x)= p_{i}\left(x-x_{i-1}\right) s_{i}+p_{i}\left(x_{i}-x\right) s_{i-1} \\
&+4\left(x-x_{i-1}\right)\left(x_{i}-x\right)\left[y_{i-(1 / 2)}-\frac{1}{2}\left(s_{i}+s_{i-1}\right)\right]  \tag{1}\\
& p_{i+1} s_{i-1}+3\left(p_{i}+p_{i+1}\right) s_{i}+p_{i} s_{i+1}=4\left(p_{i+1} y_{i-(1 / 2)}+p_{i} y_{i+(1,2)}\right) \tag{2}
\end{align*}
$$

and

$$
\begin{equation*}
p_{i} \lambda_{i-1}+3\left(p_{i}+p_{i+1}\right) \lambda_{i}+p_{i+1} \lambda_{i+1}=8\left(y_{i+(1 / 2)}-y_{i-(1 ; 2)}\right), \tag{3}
\end{equation*}
$$

where $s\left(x_{i}\right)=s_{i}, s^{\prime}\left(x_{i}\right)=\lambda_{i}, x_{i}-x_{i-1}=p_{i}$ and $p$-maximum of $p_{i}$ over all $i$. Replacing $\lambda_{i}$ by $e_{i}^{\prime}+y_{i}^{\prime}$ in (3) we see after an appropriate application of Taylor's Theorem that the right-hand side of (3) becomes,

$$
\begin{aligned}
& p_{i+1}\left(y^{\prime}\left(\theta_{2}\right)-y_{i+1}^{\prime}\right)+3 p_{i+1}\left(y^{\prime}\left(\theta_{2}\right)-y_{i}^{\prime}\right) \\
& \quad+3 p_{i}\left(y^{\prime}\left(\theta_{1}\right)-y_{i}^{\prime}\right)+p_{i}\left(y^{\prime}\left(\theta_{1}\right)-y_{i-1}^{\prime}\right)
\end{aligned}
$$

where $\theta_{1} \in\left(x_{i-(1 ; 2)}, x_{i}\right)$ and $\theta_{2} \in\left(x_{i}, x_{i+11 ; 2)}\right)$. This combined with (3) leads to (i).

For the next two results we assume without loss of generality that, in $\left(x_{i-1}, x_{i}\right)$, the maximum of $e^{\prime}(x)$ (respectively, $e(x)$ ) is assumed at a point $>x_{s-11: 21}$. We see that

$$
\begin{aligned}
p_{i} e^{\prime}(x)= & \left(x_{i}-x\right) e_{i-1}^{\prime}+\left(x-x_{i-1}\right) e_{i}^{\prime}+\left(x_{i}-x\right)\left(y_{i-1}^{\prime}-y_{i-(122 i}^{\prime}\right) \\
& +\left(x-x_{i-1}\right)\left(y_{i}^{\prime}-y^{\prime}(x)\right)-\left(x_{i}-x\right)\left(y^{\prime}(x)-y_{i-11 / 2)}^{\prime}\right)
\end{aligned}
$$

Thus

$$
\left|e^{\prime}(x)\right| \leqslant\left\|e_{i}^{\prime}\right\|+\left[1+\left(x_{i}-x\right) / p_{i}\right] w\left(y^{\prime}, p / 2\right)
$$

which directly gives (ii).
Setting $x-x_{i-1}=a$ and $x_{i}-x=b$, we see from (1), after applying Taylor's Theorem, that

$$
\begin{aligned}
p_{i}^{2} e(x)= & (a-b)\left[a e_{i}-b e_{i-1}+b\left\{a\left(y^{\prime}\left(\theta_{3}\right)-y_{i-(1 / 2}^{\prime}\right)\right.\right. \\
& \left.\left.+\frac{1}{2}(a+b)\left(y^{\prime}\left(\theta_{1}\right)-y_{i-\{1 / 2)}^{\prime}\right)+\frac{1}{2}(3 a+b)\left(y_{i-(1 / 2)}^{\prime}-y^{\prime}\left(\theta_{2}\right)\right)\right\}\right],
\end{aligned}
$$

where $\theta_{1} \in\left(x_{i-1}, x_{i-(1 / 2)}\right)$ and $\theta_{2}, \theta_{3} \in\left(x_{\left.i-(1)^{2}\right)}, x_{i}\right)$. Thus

$$
|e(x)| \leqslant \frac{(a-b)}{p_{i}}\left[\left\|e_{i}\right\|+\frac{b(a+b)+2 a b}{p_{i}} w\left(y^{\prime}, p / 2\right)\right]
$$

which leads to (iii) when we appeal to the estimate $\left\|e_{i}\right\| \leqslant p u\left(y^{\prime}, p / 2\right)$ as obtained by Marsden [1, Theorem 2.2].
