Direct cost estimates include medical expenditures, traffic costs, and caregiver’s cost. Indirect costs representing the loss of production include lost workdays due to illness and lost earnings due to premature death and are estimated based on human capital theory. The cost estimates are reported in USA Purchasing Power Parity Dollars and calculated at three different discount rates (0%, 3% and 5%). The major data sources are National Health Insurance Statistical Yearbook, Annual Report on the Cause of Death Statistics, and Survey Report on Wage Structure. We also use other information such as the Korean Statistical Information System. RESULTS: The cost of diseases in Korea in 2001 is 50.0 billion US PPP$/ (hereafter) based on 0% discount rate. The estimate represents approximately 6.6% of GDP or $1627 per person. Direct and indirect costs are estimated at $26.1 billion (32.2% of total cost) and $23.9 billion (47.8%), respectively. And it is found that the cost at aged 40 – 49 accounts for the largest proportion (22.2%) at age group and the cost of the male is 23.6% higher than that of the female. In the case of major diseases, the total cost of neoplasms is $8.2 billion; $7.4 billion in diseases of digestive system; $6.5 billion in diseases of respiratory system; and $5.9 billion in diseases of circulatory system. CONCLUSIONS: This study can be expected to provide valuable information for determining intervention and funding priorities, and planning for health policy.

HEALTH POLICY—Health Care Decision Studies

PEER PRESSURE IN HEALTH CARE

Lo JC

The Institute of Economics, Academia Sinica, Taiwan, Taipei, Taiwan

OBJECTIVES: Past literature has shown that peer pressure shows significant effects on the probability that a young adult will commit a crime, a juvenile will start to smoke, a student will begin to study hard, etc. Almost all of the activities documented so far discuss the phenomena that one’s behavior is influenced by others around him and has an impact on one’s own self. However, in the health care field, if peer pressure among physicians does exist, then it has an impact not only on the physicians alone, but also on the patients as well. Therefore, this topic deserves special attention, but as far as we know, there has not been any related research. In this study we will investigate the impact of peer pressure on the cesarean-section decision.

METHODS: Taiwan implemented its National Health Insurance (NHI) in 1995. It is a single-payer system with a pre-determined fee schedule. The health delivery system is a closed one with physicians being employed by hospitals, and a physician’s income depends primarily upon the services he provides. A logistic model is employed, with 1 indicating that the delivery was performed by cesarean section, utilizing Taiwan’s NHI in-patient claim data from 1997 to 2001. The average cesarean section rate of the fellow obstetricians in the same hospital for the previous month is treated as peer pressure. RESULTS: After taking into consideration the clinical indications, peer pressure shows a significant positive influence on an obstetrician’s cesarean section decision. CONCLUSIONS: Whether the same phenomenon holds true for other types of care and for other type of health care system has yet to be explored. Nevertheless, strategies to eliminate its influence are necessary in order to provide a better quality of care.
