Received 23 June 1980

## 1. Introduction

In 1975 it was shown that cytidine-5'-phosphate stimulates the $E$. coli ribosomal reaction of pA-Met $\leftarrow \mathrm{f}$ with Phe-tRNA ${ }^{\text {Phe }}$ or C-A-C-C-A-Phe [1]. The stimulating effect of cytidine $5^{\prime}$-phosphate is explained by the tendency of this nucleotide to be bound to the area of the donor site of the peptidyl transferase centre occupied in an ordinary process by the penultimate $3^{\prime}$-terminal nucleotide of peptidyl-tRNA [2-4]. By an identical mechanism cytidine $5^{\prime}$-phosphate also stimulates the reactions catalyzed by 50 S subunits of $E$. coli ribosomes [5] and by rat liver ribosomes [6]. All these facts indicate some allosteric effects taking place in the peptidyl transferase centre as a result of the occupancy of the ribosomal A- and $P$-site.

Several experiments have been reported which indicate that the activity of one ribosomal site can be influenced by the reaction taking place in the other site of the ribosomes (reviewed [7]). Among them the dependence of activity of puromycin [8] and other model acceptors [9] upon the nature of peptide donor should be mentioned. The peptidyl-tRNA bound to the donor site stimulates binding of the complex aminoacyl-tRNA + EF-I + GTP to rabbit

[^0]reticulocyte ribosomes [10]. The stimulating action is displayed if a peptide residue is located at the $3^{\prime}$-hydroxyl, but not at the $2^{\prime}$-hydroxyl of the terminal adenosine of tRNA. The stimulation of acceptor pentanucleotide substrate binding to 50 S subunits of $E$. coli ribosomes by tRNA and C-C-A trinucleotide was also observed [11].

We report here on the systematic investigation of the interrelation between the model substrates of the peptidyl transferase center of $E$. coli ribosomes under the 'fragment reaction' conditions. We can show that the presence of model substrate-like inhibitor on one of the sites does not change the equilibrium association constant ( $K_{\mathrm{a}}$ ) of the second model substrate binding to the neighbouring site and practically does not increase the fraction of ribosomes taking part in substrate binding. However, the catalytic rate constants ( $k_{\text {cat }}$ ) of the reactions of C-A-C-C-A-Phe with $\mathrm{pA}-\mathrm{Met} \leftarrow \mathrm{f}, \mathrm{pA}-\mathrm{Le} u \leftarrow \mathrm{f}$ or $\mathrm{pA}-\mathrm{Phe} \leftarrow \mathrm{f}$ are increased by 1.5 orders of magnitude in the presence of cytidine 5'-phosphate.

## 2. Materials and methods

### 2.1. Materials

The ribosomes were isolated from Escherichia coli MRE-600 by centrifugation in a sucrose gradient in a zonal rotor, according to [12] and activated prior to the experiment by heating at $40^{\circ} \mathrm{C}$ for 10 min . C-A-C-C-A $\left[{ }^{3} \mathrm{H}\right]$ Phe, C-A-C-C-A- $\left[{ }^{14} \mathrm{C}\right]$ Phe and C-A-C-C-A- $\left[{ }^{14} \mathrm{C}\right]$ Val were obtained by $\mathrm{T}_{1}$ RNase hydrolysis of corresponding aminoacyl-tRNAs. Specific radioactivity for [ ${ }^{14}$ ]phenylalanine was $270 \mathrm{mCi} / \mathrm{mmol}$
(UVVVR, Czechoslovakia), for [ $\left.{ }^{3} \mathrm{H}\right]$ phenylalanine 6 $\mathrm{Ci} / \mathrm{mmol}$ (Isotop, USSR) and for $\left[{ }^{14} \mathrm{C}\right]$ valine 124 $\mathrm{mCi} / \mathrm{mmol}$ (UVVVR). C-A-C-C-A $\left(3^{\prime} \mathrm{NH}-\left[{ }^{14} \mathrm{C}\right]-\right.$ Phe $\leftarrow \mathrm{Ac})$ was obtained from $\mathrm{RNN} \Lambda^{\text {Phe }}$-C-C-A $\left(3^{\prime} \mathrm{NH}-\right.$ [ $\left.{ }^{14} \mathrm{C}\right]$ Phe) [13] by acetylation with acetanhydride and subsequent hydrolysis with $T_{1}$ RNase. Specific radioactivity for $\left[{ }^{14} \mathrm{C}\right]$ phenylalanine was 513 mCi / mmol (Amersham, England). Aminoacyl and acetylaminoacyl oligonucleotides were purified by electrophoresis on Whatman no. 1 or 3MM paper with $0.5 \%$ pyridine and $5 \%$ acetic acid ( pH 3.5 ) buffer, for 2 h with a gradient of $53 \mathrm{~V} / \mathrm{cm}$. The yield of acetylation was tested prior to use as in [14]. pA-Met $\leftarrow \mathrm{f}, \mathrm{pA}-\mathrm{Phe}-\mathrm{f}$, $\mathrm{pA}-$ Leu $\leftarrow \mathrm{f}$ and $\mathrm{pA}\left(3^{\prime} \mathrm{NH}-\mathrm{Met} \leftarrow \mathrm{f}\right)$ were synthesized according to [15] and [16], respectively.

### 2.2. Methods

The binding of $\left.\mathrm{C}-\mathrm{A} \cdot \mathrm{C}-\mathrm{C}-\mathrm{A}\left(3^{\prime} \cdot \mathrm{NH}-{ }^{14} \mathrm{C}\right] \mathrm{Phe}-\mathrm{Ac}\right)$, C-A-C-C-A- $\left[{ }^{3} \mathrm{H}\right]$ Phe and C-A-C-C-A- $\left[{ }^{14} \mathrm{C}\right]$ Val to ribosomes was examined according to [14]. The 0.05 ml incubation mixture contained 0.06 M Tris- HCl buffer ( pH 7.5 ), $0.2 \mathrm{M} \mathrm{KCl}, 0.01 \mathrm{M} \mathrm{MgCl}_{2}$ and $40 \%$ (v/v) ethanol; the amounts of ribosomes and substrates are indicated in the figure legends.

The transfer reaction in the presence of cytidine $5^{\prime}$-phosphate was done at $0^{\circ} \mathrm{C}$ for 10 min . In the absence of cytidine $5^{\prime}$-phosphate the reaction was performed at $0^{\circ} \mathrm{C}$ for 20 min . Reaction mixture ( 150 $\mu \mathrm{l}$ ) contained: 1 mM pA-Met $\leftarrow \mathrm{f}, \mathrm{pA}-\mathrm{Phe} \leftarrow \mathrm{f}$ or pA -Leu $\leftarrow \mathrm{f}, 7 \times 10^{-7} \mathrm{M}$ ribosomes and $8 \times 10^{-8}$ _$2.4 \times 10^{-7} \mathrm{MC}-\mathrm{A}-\mathrm{C}-\mathrm{C}-\mathrm{A}-\left[{ }^{14} \mathrm{C}\right]$ Phe. The reaction products were extracted with ethyl acetate and the radio-

Fig.1. Plot of $1 / \bar{v}$ vs $1 / A$ for the binding of C-A-C-C-A ( $3^{\prime} \mathrm{NH}-$ $\left[{ }^{14} \mathrm{C}\right]-\mathrm{Phe}-\mathrm{Ac}$ ). The amount of substrate was varied from $3.1-35.7 \mathrm{pmol}$; the amount of ribosomes was 12.5 pmol . $\bar{v}, a v$. no. substrate molecules bount/ribosome; $A$, concentration of unbound substrate.
activity was determined [2,3]. Calculation of $K_{\mathrm{a}}, K_{\mathrm{m}}$, $\alpha$ and $k_{\text {cat }}$ were done as in [14,17].

## 3. Results

### 3.1. The binding of $C-A-C-C-A\left(3^{\prime} N H-\left[{ }^{14} C l P h e \leftarrow A c\right)\right.$ to ribosomes

In fig. 1 the measurements used for the determination of $K_{\mathrm{a}}$ of the binding of the C-A-C-C-A $\left(3^{\prime} \mathrm{NH}-\right.$ $\left[{ }^{14} \mathrm{C}\right] \mathrm{Phe} \mathrm{Ac}$ ) fragment to the ribosomes are presented. The ratio of C-A-C-C-A ( $\left.3^{\prime} \mathrm{NH} \cdot\left[{ }^{14} \mathrm{C}\right] \mathrm{Phe} \leftarrow \mathrm{Ac}\right)$ : ribosome was varied from $0.25-2.9$. The $K_{\mathrm{a}}$ calculated from this data is $1.4 \times 10^{6} \mathrm{M}^{-1}$ and the fraction of ribosomes capable of binding the substrate $\alpha$ is $85 \%$. The statistical treatment of a number of experiments gives $K_{\mathrm{a}}=1.3( \pm 0.26) \times 10^{6} \mathrm{M}^{-1}$ and $\alpha=80 \pm$ $20 \%$.

### 3.2. Binding of $C-A-C-C-A\left(3^{\prime} N H-\left[{ }^{14} C\right] P h e \leftarrow A c\right)$ to ribosomes in the presence of acceptor substrates.

Fig. 2 shows the binding of C-A-C-C-A $\left(3^{\prime} \mathrm{NH} \cdot\left[{ }^{14} \mathrm{C}\right]\right.$ -

Fig.2. The C-A-C-C-A(3'NH-[ $\left.{ }^{14} \mathrm{C}\right]$ Phe $\left.\leftarrow \mathrm{Ac}\right)$ binding in the presence of increasing amounts of C-A-C-C-A- $\left.{ }^{3} \mathrm{H}\right]$ Phe (A) and puromycin (B). Incubation mixture contained 12.15 pmol ribosomes and 15 pmol donor substrate.

Fig.3. Binding of $\mathrm{C}-\mathrm{A}-\mathrm{C}-\mathrm{C}-\mathrm{A}-\left[{ }^{3} \mathrm{H}\right]$ Phe in the presence of increasing amounts of $\mathrm{C}-\mathrm{A}-\mathrm{C}-\mathrm{C}-\mathrm{A}\left(3^{\prime} \mathrm{NH}-\left[{ }^{14} \mathrm{C}\right] \mathrm{Ph} \leftarrow \mathrm{Ac}\right)$. Incubation mixture contained 17 pmol ribosomes and 18.3 pmol acceptor substrate.

Phe $\leftarrow \mathrm{Ac}$ ) in the presence of increasing amounts of C-A-C-C-A- $\left.{ }^{3} \mathrm{H}\right]$ Phe (A) and puromycin (B). It can be seen that no significant effect of acceptor site substrates on C-A-C-C-A $\left(3^{\prime} \mathrm{NH}-\left[{ }^{14} \mathrm{C}\right]\right.$ Phe $\left.\leftarrow \mathrm{Ac}\right)$ binding was observed even when ribosomes were saturated with C-A-C-C-A- $\left.{ }^{3} \mathrm{H}\right]$ Phe up to $90 \%$. For C-A-C-C-A $3^{\prime} \mathrm{NH}-$ $\left[{ }^{14} \mathrm{C}\right]$ Phe $\left.\leftarrow \mathrm{Ac}\right) K_{\mathrm{a}}$ was $1.50( \pm 0.44) \times 10^{6} \mathrm{M}^{-1}$ and $\alpha$ was $80 \pm 20 \%$. These two parameters were practically the same independently of the presence or absence of the acceptor substrate.

### 3.3. The binding of $C-A-C-C-A-I^{3} H / P h e$ and $C-A-C$ -

 $C-A-{ }^{14} C l$ Val to ribosomes in the presence of C-A-C-C-A $\left(3^{\prime} N H-\left[{ }^{14} C\right] P h e \leftarrow A c\right), p A\left(3^{\prime} N H-\right.$ Met $\leftarrow$ f) and cytidine $5^{\prime}$-phosphateFig. 3 shows the binding of acceptor site substrate, C-A-C-C-A- $\left[{ }^{3} \mathrm{H}\right]$ Phe, in the presence of increasing amounts of C-A-C-C-A( $3^{\prime} \mathrm{NH}-\left[{ }^{14} \mathrm{C}\right]$ Phe $\left.\leftarrow \mathrm{Ac}\right)$. The saturation of ribosomes with C-A-C-C-A $\left(3^{\prime} \mathrm{NH}-\left[{ }^{14} \mathrm{C}\right]\right.$ Phe $\leftarrow \Lambda$ c) was up to $40 \%$. There is no significant stimulation of C-A-C-C-A- $\left[{ }^{3} \mathrm{H}\right]$ Phe binding in the presence of C-A-C-C-A ( $3^{\prime} \mathrm{NH}-\left[{ }^{14} \mathrm{C} \mid \mathrm{Ph}-\leftarrow \mathrm{Ac}\right)$; for $\mathrm{C}-\mathrm{A}-\mathrm{C}-\mathrm{C}-\mathrm{A}-$ $\left[{ }^{3} \mathrm{H}\right]$ Phe $K_{\mathrm{a}}=(5.0 \pm 2.0) \times 10^{5} \mathrm{M}^{-1}$ and $\alpha=70 \pm$ $10 \%$ either in the presence of C-A-C-C-A $\left(3^{\prime} \mathrm{NH} \cdot\left[{ }^{14} \mathrm{C}\right]\right.$ $\mathrm{Phe} \leftarrow \mathrm{A} c$ ) or in its absence.

Fig. 4 summarizes the data on C-A-C-C-A- $\left[{ }^{3} \mathrm{H}\right]$ Phe binding in the presence of $\mathrm{pA}\left(3^{\prime} \mathrm{NH}-\mathrm{Met} \leftarrow \mathrm{f}\right)$ or cyti-

Fig.4. The C-A-C-C-A-[ $\left.{ }^{3} \mathrm{H}\right]$ Phe binding in the presence of increasing amounts of $\mathrm{pA}\left(\mathbf{3}^{\prime} \mathrm{NH}-\mathrm{Met} \leftarrow \mathrm{f}\right)$ (o) or $\mathrm{pC}(\bullet)$. Each tube contained 17 pmol ribosomes and 18.3 pmol C-A-C-C-A- $\left[{ }^{3} \mathrm{H}\right]$ Phe.
dine $5^{\prime}$-phosphate. In both cases the compounds under investigation do not affect the acceptor binding. At concentrations of $\mathrm{pA}\left(3^{\prime} \mathrm{NH}-\mathrm{Met}-\mathrm{f}\right)$ or cytidine $5^{\prime}$-phosphate higher than $1 \times 10^{-3} \mathrm{M}$ an inhibition of C-A-C-C-A- $\left[{ }^{3} \mathrm{H}\right]$ Phe binding to the ribosomes can occur. This is due to competition with the acceptor substrate. Similarly the binding of C-A-C-C-A$\left[{ }^{3} \mathrm{H}\right] \mathrm{Val}$ to ribosomes was stimulated by neither $\mathrm{pA}\left(3^{\prime} \mathrm{NH}-\mathrm{Met} \leftarrow \mathrm{f}\right.$ ) nor cytidine-5'-phosphate (not shown).
3.4. $\mathrm{K}_{m}$ and $\mathrm{k}_{\text {cat }}$ of the reactions of model substrates $K_{\mathrm{m}}$ and $k_{\text {cat }}$ of the ribosomal reaction of the model peptide donors with C-A-C-C-A- $\left[{ }^{14} \mathrm{C}\right]$ Phe are summarized in table 1. The $K_{\mathrm{m}}$ values are about the same in the presence or absence of cytidine 5 '-phosphate. However, the $k_{\text {cat }}$ values were stimulated by 1.5 orders of magnitude by the presence of cytidine $5^{\prime}$-phosphate.

## 4. Discussion

As seen in fig. $1 \mathrm{C}-\mathrm{A}-\mathrm{C} \cdot \mathrm{C}-\mathrm{A}\left(3^{\prime} \mathrm{NH}-\left[{ }^{14} \mathrm{C}\right] \mathrm{Phe} \leftarrow \mathrm{Ac}\right)$ is bound only to a single ribosomal site. It can be confirmed that this site is the donor site. Since the fragment C-A.C.C-A ( 3 ' $\mathrm{NH}-\left[{ }^{14} \mathrm{C}\right]$ Phe $\leftarrow \mathrm{Ac}$ ) does not inhibit the binding of acceptor substrate C-A-C-C-A$\left[{ }^{3} \mathrm{H}\right]$ Phe, its binding is directed to the P -site of the ribosomal peptidyl transferase center. In addition we have shown that the fragments of peptidyl-tRNA C-C-A (3'NH-Leu $\leftarrow$ f), C-A $\left(3^{\prime} \mathrm{NH}-\mathrm{Met} \leftarrow \mathrm{f}\right)$ and $\mathrm{pA}\left(3^{\prime} \mathrm{NH}-\right.$ $\mathrm{Met} \leqslant \mathrm{f})$ are bound to the donor site of the peptidyl transferase centre [14].

Table 1
Effect of cytidine $5^{\prime}$-phosphate ( pC ) on $k_{\mathrm{cat}}$ and $K_{\mathrm{m}}$ in the reaction of model donors with C-A-C-C-A-[ $\left.{ }^{14} \mathrm{C}\right]$ Phe

| Substrate | With pC |  | Without pC |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $K_{\mathrm{M}}\left(\mathrm{M}^{-1} \times 10^{7}\right)$ | $k_{\text {cat }}\left(\mathrm{s}^{-1} \times 10^{4}\right)$ | $K_{\mathrm{m}}\left(\mathrm{M}^{-1} \times 10^{7}\right)$ | $k_{\text {cat }}\left(\mathrm{s}^{-1} \times 10^{6}\right)$ |
| pA-Met $\leftarrow \mathrm{f}$ | 10 | 10 | 3-10 | 20-50 |
| pA-Leu-f | 2-2.5 | 2-3 | 1-3 | 5-10 |
| pA-Phe $\leftarrow \mathrm{f}$ | 2-2.5 | 1-2 | $<1$ | <5 |

Fig.2-4 show that under the conditions used the acceptor substrate of the peptidyl transferase centre bound to the acceptor site has practically no effect on $K_{\mathrm{a}}$ and $\alpha$ of the donor substrate and vice versa. At the same time the fact that $k_{\text {cat }}$ of the reactions of model donors with C-A-C-C-A-Phe is increased by 1.5 orders of magnitude (table 1) in the presence of cytidine $5^{\prime}$-phosphate implies that this nucleotide leads to the conversion of a low-activity ribosomal complex into high-activity one. Probably the binding of cytidine $5^{\prime}$-phosphate produces some conformational changes in the peptidyl transferase centre facilitating the transpeptidation reaction.

It is possible that the cytidine $5^{\prime}$-phosphate binding locus is not the only area that produces the conformational changes in the peptidyl transferase centre. However, there is no area of binding for the cytidylic residuc or residues in the acceptor site capable of transforming a low activity complex into a high activity one. This follows from the fact that cytidine $5^{\prime}$-phosphate does not stimulate the activity of model acceptors (puromycin [1,2] or $3^{\prime}\left(2^{\prime}\right)$-O-valyl-adenosine, A-Val; not shown).

These results clearly show that the peptidyl transferase centre is not a rigid matrix binding only its substrates, but it fulfills a more complex function and plays an active role in the process of transpeptidation.

## Acknowledgements

Part of this work was performed during the stay of A. A. K. at Max-Planck-Institut für experimentelle Medizin in Göttingen. We thank the Deutsche Forschungsgemeinschaft for a financial support during his visit to the FRG. We are indebted to Professor F. Cramer and Dr D. Gauss for support and cooperation in course of our investigations.
