# Simultaneous Best Approximations with Two Polynomials 

David A. Sprecher<br>Department of Mathematics, University of California, Santa Barbara, California 93106

## 1. The Problem

The following problem was posed by T. J. Rivlin [1]: Let $\mathscr{C}$ stand for the space of continuous real valued functions on the interval [0, 1]; let $E_{j}(f)$ represent the Chebyshev degree of approximation to $f$ by algebraic polynomials of degree $j$. Characterize the $n$-tuples $\left\{p_{0}, p_{1}, \ldots, p_{n-1}\right\}$ of algebraic polynomials $p_{j}$, where $\operatorname{deg} p_{j}=j$, which have the property that there is a function $f \in \mathscr{C}$ such that

$$
\begin{equation*}
E_{j}(f)=\left\|f-p_{j}\right\| \tag{1}
\end{equation*}
$$

for $j=0,1,2, \ldots, n-1$, the norm on the right side being the uniform norm.
In this note we prove the following related
Theorem. Given polynomials $p_{m}$ and $p_{n}, 0 \leqslant m<n$, there is a function $f \in \mathscr{C}$ which satisfies (1) for the integers $j=m$ and $j=n$ if and only if the polynomial $p_{n}-p_{m}$ changes sign at least $m+1$ times in $[0,1]$.

The linear case $m=0, n=1$ was proved by Deutsch, Morris and Singer in [2]. Our only excuse for reproving this case is that our proof is very short. The necessity of the condition in the theorem was stated and proved by Rivlin [1].

## 2. Proof of the Case $m=0, n=1$

To verify the sufficiency of the condition let us consider polynomials $p_{0}(x)=c$ and $p_{1}(x)=a x+b(a \neq 0)$ such that at $+b=c$ for some $t, 0<t<1$. Then the equality

$$
\frac{1}{2}\left[p_{1}(t-\delta)+p_{1}(t+\delta)\right]=c
$$

holds for each number $\delta$, and we fix a $\delta$ such that $0<\delta<\min \{t, 1-t\}$. Let us suppose that $a>0$ and put

$$
\alpha=\max \{|a+b-c|,|b-c|\} .
$$

If $f \in \mathscr{C}$ is the piecewise linear function with vertices

$$
(0, c-\alpha) \quad(t-\delta, c-\alpha) \quad(t+\delta, c+\alpha) \quad\left(1, p_{1}(t+\delta)\right)
$$

(see Fig. 1), then (1) is easily seen to hold for $j=0,1$. The desired $f$ in case $a<0$ is obtained from the above construction by the substitution $x=1-y$.

The necessity of the asserted sign change is demonstrated as follows: let a function $f \in \mathscr{C}$ and polynomials $p_{0}, p_{1}$ satisfy (1). If we put

$$
g_{j}=f-p_{j} \quad(j=0,1),
$$

then it is an elementary observation that

$$
\begin{equation*}
\max g_{j}+\min g_{j}=0 \quad(j=0,1) \tag{2}
\end{equation*}
$$

Fig. 1.
where the maximum and minimum are taken over $[0,1]$. If, say, $g_{1}>g_{2}$ on $(0,1)$, then $\max g_{1}>\max g_{2}$ and $\min g_{1}>\min g_{2}$, so that

$$
\max g_{1}+\min g_{1}>\max g_{2}+\min g_{2}
$$

But this implies that (2) fails to be true for $g_{1}$ or $g_{2}$. Clearly, one arrives at the same conclusion if $g_{2}>g_{1}$ on $(0,1)$ and the necessity of the sign change is hereby proved.

## 3. Proof of the Case $m=0, n>1$

Let $p_{n}\left(x_{0}\right)=c$ for some point $0<x_{0}<1$. Then there are points $0<x_{1}<$ $x_{0}<x_{2}<1$ such that

$$
\frac{1}{2}\left[p_{n}\left(x_{1}\right)+p_{n}\left(x_{2}\right)\right]=c
$$

we may assume without loss of generality that $p_{n}\left(x_{2}\right)>c$. We introduce the polynomials

$$
\begin{align*}
& p_{n}^{-}(x)=p_{n}(x)-\left[p_{n}\left(x_{1}\right)+\left\|p_{n}\right\|-c\right], \\
& p_{n}^{+}(x)=p_{n}(x)+\left[p_{n}\left(x_{1}\right)+\left\|p_{n}\right\|-c\right], \tag{3}
\end{align*}
$$

satisfying

$$
\frac{1}{2}\left[p_{n}^{-}(x)+p_{n}^{+}(x)\right]=p_{n}(x)
$$

Let

$$
k= \begin{cases}n+3 & \text { if } n \text { is odd } \\ n+4 & \text { if } n \text { is even }\end{cases}
$$

and fix points

$$
x_{1}=u_{1}<u_{2}<u_{2}<\ldots<u_{k-1}<u_{k}=x_{2}
$$

(see Fig. 2). The function

$$
g(x)=\left\{\begin{align*}
& \frac{u_{2 j}-x}{u_{2 j}-u_{2 j-1}} p_{n}-(x)+\frac{x-u_{2 j-1}}{u_{2 j}-u_{2 j-1}} p_{n}{ }^{+}(x)  \tag{4}\\
&\left(u_{2 j-1} \leqslant x \leqslant u_{2 j}, j=1,2, \ldots, \frac{k}{2}\right) \\
& \frac{u_{2 j+1}-x}{u_{2 j+1}-u_{2 j}} p_{n}{ }^{+}(x)+\frac{x-u_{2 j}}{u_{2 j+1}-u_{2 j}} p_{n}-(x) \\
&\left(u_{2 j} \leqslant x \leqslant u_{2 j+1}, j=1,2, \ldots, \frac{k}{2}-1\right)
\end{align*}\right.
$$

which is defined and continuous on the interval $\left[x_{1}, x_{2}\right]$, is best approximated in the class of all $n$-degree algebraic polynomials by $p_{n}(x)$. This follows from the facts that

$$
\begin{aligned}
& p_{n}\left(u_{2 j-1}\right)-g\left(u_{2 j-1}\right)=p_{n}\left(u_{2 j-1}\right)-p_{n}^{-}\left(u_{2 j 11}\right)=p_{n}\left(x_{1}\right)+\left\|p_{n}\right\|-c \\
& \quad\left(j=1,2, \ldots, \frac{k}{2}\right), \\
& p_{n}\left(u_{2 j}\right)-g\left(u_{2 j}\right)=p_{n}\left(u_{2 j}\right)-p_{n}^{+}\left(u_{2 j}\right)=-\left[p_{n}\left(x_{1}\right)+\left\|p_{n}\right\|-c\right] \\
& \left(j=1,2, \ldots, \frac{k}{2}-1\right),
\end{aligned}
$$

and

$$
\left\|g-p_{n}\right\|=p_{n}\left(x_{1}\right)+\left\|p_{n}\right\|-c
$$

as shown by a simple calculation. We let

$$
f(x)= \begin{cases}\frac{x_{1}-x}{x_{1}} p_{n}(x)+\frac{x}{x_{1}} p_{n}^{-}(x) & \left(0 \leqslant x \leqslant x_{1}\right) \\ g(x) & \left(x_{1} \leqslant x \leqslant x_{2}\right) \\ \frac{1-x}{1-x_{2}} p_{n}^{+}(x)+\frac{x-x_{2}}{1-x_{2}} p_{n}(x) & \left(x_{2} \leqslant x \leqslant 1\right)\end{cases}
$$

Then

$$
\left\|f-p_{n}\right\|=\left\|g-p_{n}\right\|
$$

so that $E_{n}(f)=\left\|f-p_{n}\right\|$. To see that $E_{0}(t)=\|f-c\|$ we observe from (3) that

$$
\begin{aligned}
& f\left(x_{1}\right)=p_{n}^{-}\left(x_{1}\right)=c-\left\|p_{n}\right\|, \\
& f\left(x_{2}\right)=p_{n}^{+}\left(x_{2}\right)=c+\left\|p_{n}\right\|,
\end{aligned}
$$

and a routine calculation shows that

$$
-\left\|p_{n}\right\| \leqslant f(x)-c \leqslant\left\|p_{n}\right\| \quad(0 \leqslant x \leqslant 1)
$$

Necessity is proved just as in the previous case.

FIG. 2.

## 4. Proof of the Case $m>0, n>1$

Consider arbitrary polynomials $p_{m}$ and $p_{n}$, with $1 \leqslant m<n$, such that $p_{n}-p_{m}$ changes sign at least $m+1$ times in $[0,1]$. Then there are points

$$
0<t_{1}<t_{2}<\ldots<t_{m+1}<1
$$

such that $p_{m}\left(t_{j}\right)=p_{n}\left(t_{j}\right)$ for $j=1,2, \ldots, m+1$. Letting $t_{0}=0$ and $t_{m+2}=1$, we put

$$
\begin{aligned}
\alpha_{j} & =\max _{t_{j} \leqslant x \leqslant t_{j+1}}\left|p_{m}(x)-p_{n}(x)\right|, \\
\alpha & =\frac{1}{2} \min \left\{\alpha_{0}, \alpha_{1}, \ldots, \alpha_{m+1}\right\}, \\
\beta & =\max \left\{\left\|p_{m}\right\|,\left\|p_{n}\right\|\right\} .
\end{aligned}
$$

Suppose $p_{n}(x) \geqslant p_{m}(x)$ for $t_{1} \leqslant x \leqslant t_{2}$ and consider the polynomials

$$
\begin{aligned}
& p_{n}^{-}(x)=p_{n}(x)-\beta, \\
& p_{n}^{+}(x)=p_{n}(x)+\beta, \\
& p_{m}^{-}(x)=p_{m}(x)-\alpha-\beta, \\
& p_{m}^{+}(x)=p_{m}(x)+\alpha+\beta .
\end{aligned}
$$

Then each of the polynomials $p_{n}{ }^{-}-p_{m}{ }^{-}$and $p_{n}{ }^{+}-p_{m}{ }^{+}$also changes sign at least $m+1$ times in [ 0,1$]$. Thus, there are $m+2$ points $x_{j}$,

$$
x_{j}<t_{j}<x_{j+1}, \quad j=1,2, \ldots, m+1
$$

such that

$$
\begin{equation*}
p_{m}^{-}\left(x_{2 k-1}\right)=p_{n}^{-}\left(x_{2 k-1}\right) \tag{5}
\end{equation*}
$$

and

$$
\begin{equation*}
p_{m}^{+}\left(x_{2 k}\right)=p_{n}^{+}\left(x_{2 k}\right) \tag{6}
\end{equation*}
$$

for all admitted values of $k$. The point $x_{2}$ can be so chosen that

$$
p_{m}^{-}(x) \leqslant p_{n}^{-}(x)<p_{n}^{+}(x) \leqslant p^{+}(x), \quad\left(x_{1} \leqslant x \leqslant x_{2}\right) .
$$

On the interval $\left[x_{1}, x_{2}\right]$ the situation is now similar to that in Case 3. Thus, let $g$ be defined as in (4). Then $p_{n}$ is its best approximation in the class of algebraic polynomials of degree $n$.

Put for each $x \in[0,1]$,

$$
\begin{aligned}
& q^{-}(x)=\max \left\{p_{m}^{-}(x), p_{n}^{-}(x)\right\}, \\
& q^{+}(x)=\min \left\{p_{m}^{+}(x), p_{n}^{+}(x)\right\} .
\end{aligned}
$$

Then

$$
\begin{aligned}
q\left(x_{2 k-1}\right) & =p_{m}^{-}\left(x_{2 k-1}\right)=p_{n}^{-}\left(x_{2 k-1}\right) \\
q^{+}\left(x_{2 k}\right) & =p_{m}^{+}\left(x_{2 k}\right)=p_{n}^{+}\left(x_{2 k}\right)
\end{aligned}
$$

(see (5) and (6)). In a manner similar to that in Case 3 we construct a function $f \in \mathscr{C}$ such that

$$
\begin{gather*}
q^{-}(x) \leqslant f(x) \leqslant q^{+}(x),  \tag{7}\\
f(x)=g(x) \quad \text { for } x_{1} \leqslant x \leqslant x_{2},  \tag{8}\\
f\left(x_{2 k-1}\right)=q^{-}\left(x_{2 k-1}\right),  \tag{9}\\
f\left(x_{2 k}\right)=q^{+}\left(x_{2 k}\right)
\end{gather*}
$$

The conditions (7) and (8) guarantee that $p_{n}$ is also the best approximation of $f$ by algebraic polynomials of degree $n$. Conditions (7) and (9) show that the best approximation to $f$ from among the algebraic polynomials of degree $m$ is $p_{m}$ : the calculations justifying this conclusion are routine and therefore omitted here.

For the necessity of the asserted sign changes we refer this time to Rivlin's proof in [1].
