**Methods:** The impact of anemia on mortality was studied, and its incremental predictive value was evaluated. Demographic, clinical, and biologic characteristics at admission, as well as treatments and mortality, were recorded for 1,410 consecutive patients with acute coronary syndromes. The incremental value of adding anemia information to risk score evaluation was determined using changes in the appropriateness of Cox models when anemia was added.

**Results:** Anemia was detected in 381 patients (27%). They were older, had more co-morbidities, had higher Global Registry of Acute Coronary Events (GRACE) risk scores, received fewer guideline-recommended treatments, and, as a result, had 4-fold higher mortality. When included in a prediction model based on the GRACE risk score, anemia remained an independent predictor of mortality. The addition of anemia improved both the discriminatory capacity and calibration of the models. According to the GRACE risk score, the population was divided into 4 groups of different risk levels of <1%, 1% to <5%, 5% to <10%, and > or =10%. The addition of anemia to the model made it possible to reclassify 9%, 43%, 47%, and 21% of patients into the different risk categories, respectively.

**Conclusion:** Our data confirmed that anemia was an independent predictive factor of mortality and had incremental predictive value to the GRACE score system for early clinical outcomes.

**Key words:** Anemia; acute coronary syndromes; risk assessment.

### 011 Insights from endogenous thrombin generation in patients undergoing percutaneous coronary intervention. A cohort study

François Schiele, Evelyne Raccadot, Nicolas Menevée, Marie-France Seronde, Vincent Descotes-Genon, Joanna Oettinger, Kais Mrabet, Romain Chopard, Jean-Pierre Bassand

**CHU Besançon, Cardiologie, Besançon, France**

**Background:** Determination of appropriate dosing of antithrombotic drugs is difficult, and clinical studies to define appropriate monitoring techniques are needed.

**Objective:** We compared the endogenous thrombin potential (ETP) in patients planning to undergo percutaneous coronary intervention (PCI) being pre-treated with a combination of two or three antiplatelet agents and with fondaparinux or unfractionated heparin (UFH). Pre-treatment was dependent upon clinical presentation. Calibrated Automated Thrombography was performed in voluntary blood donors and in patients submitted to PCI. Thrombin generation was studied in platelet poor plasma by a fluorimetric technique.

**Patients/Methods:** A total of 152 patients were included. Group 1 patients were pre-treated with aspirin alone, group 2 were pre-treated with aspirin and clopidogrel, group 3 were treated with a combination of aspirin, clopidogrel, and 2.5 mg fondaparinux, group 4 were treated with aspirin, clopidogrel, 2.5 mg fondaparinux, and tirofiban, and group 5 received a bolus of 50 IU/kg UFH plus antiplatelet agents.

**Results:** Compared with voluntary blood donors, there was a significant decrease in ETP in group 2. The addition of fondaparinux (group 3) induced a 24% decrease in ETP; a further 25% decrease in ETP was observed between groups 3 and 4. No thrombin generation was observed after UFH treatment.

**Conclusion:** Assessment of thrombin generation is potentially very useful in the setting of PCI, where a combination of antiplatelet agents and an anti-coagulant is mandatory.

### 012 ST-segment resolution following primary percutaneous coronary intervention for STEMI: relationship with infarct size and microvascular obstruction assessed by MRI

Gérard Roumain, Philippe Germain, Olivier Morel, Annie Trinh, Laurence Jesel, Bogdan Radulescu, Gérald Rouill, Michel Chauvin, Pierre Bareiss, Patrick Ohlmann

**Hôpitaux Universitaires de Strasbourg, Pôle cardiovasculaire, Strasbourg, France**

**Background:** Cardiac magnetic resonance imaging (MRI) is the gold standard to quantify the infarct size and the extent of microvascular obstruction in ST-elevation myocardial infarction (STEMI). ST-segment resolution (STR) after primary percutaneous intervention (PCI) is currently used to assess the reperfusion quality in the acute phase myocardial infarction. The relation between STR and microvascular obstruction evaluated by MRI is unknown. The aim of this study was to determine the relationship between the STR resolution, the infarct size and the extend of microvascular obstruction.

**Methods:** 41 patients undergoing primary PCI for STEMI within 6 hours of symptom onset were prospectively included. ST-segment resolution was evaluated one hour after reperfusion. MRI was performed in all patients. Complete STR was defined as a STR>70%.

**Results:** Mean age of the patients was 54 Â± 12 yo, 85 waer males. The percent of infarct size was 18.6 Â±16% of the left ventricular volume. Microvascular obstruction was present in 68% of patients. Mean STR was 59 Â± 39% and 14 patients (34%) presented complete STR. A large infarct size (> 75% percentile) was associated with anterior localisation and left descending artery obstruction. STR significantly correlated with infarct size measured by MRI (r=0.38, p=0.026). Incomplete STR (<70%) predicted large infarct size with a sensitivity of 78%, a specificity of 42% and high degree of microvascular obstruction with sensitivity of 80% and specificity of 45%. Complete STR after PCI is a strong prognostic marker of large infarct size and high degree of micro vascular obstruction.

### 013 Pre-infarction angina and cardiovascular complications in non ST segment elevation myocardial infarction: Data from the RICO survey

Marc Zeller, Jean-Claude Beer, Patrick Ohlmann, Romain Gauthier, Michel Chauvin, Pierre Bareiss, Patrick Ohlmann

**Laboratoire de Physiopathologie et Pharmacologie Cardiovasculaires Experimentales, Dijon, France**

**Background:** The presence of preinfarction angina (PIA) has been shown to confer cardioprotection after ST segment elevation myocardial infarction (MI). However, the impact of PIA in non ST segment elevation (NSTEMI) remains to be determined.

**Patients and Methods:** From the obseRvatoire des Infarctus de Côte d’Or (RICO) survey, 1541 consecutive patients admitted in intensive care unit with a first NSTEMI were included in the study. Patients who experienced chest pain <7 days before the episode leading to admission were defined as having PIA. Patients presenting with PIA were compared with patients without PIA. Prehospital resuscitated cardiac arrest (RCA), incidence of in-hospital ventricu...
