# A Remark on Finite Transducers 

M. P. Schützenberger<br>Faculte des Sciences, Rue de la Trinite, Poitiers, France

## I. INTRODUCTION

In this note we consider a very restricted class of transducers, i.e., of automata which transform finite input words into finite output words (cf. Moore, 1956). The simplest case is the transformation consisting in the replacement of every input letter $x$ by an output word $\eta(x)$ which is eventually the empty word $e_{Y}$. Algebraically, since the set $F_{X}\left(F_{Y}\right)$ of all finite input (output) words is the free monoid (Chevalley, 1956) generated by the input alphabet $X=\{x\}$ (the output alphabet $Y=\{y\}$ ), this transformation is simply an homomorphism $\eta: F_{X} \rightarrow F_{Y}$.

If $\eta$ is such that $\eta(f)=\eta\left(f^{\prime}\right)$ only if $f=f^{\prime}$, it is called an encoding (with unique decipherability) and then $\eta$ is an isomorphism.

Next in simplicity are the transformations realized by a conventional [one way, one tape (Rabin and Scott, 1959)] automaton supplemented by a printing device (Huffman, 1959). Upon reading $x$ on the input tape and, accordingly, going from the state $s$ to the state $s^{\prime}=s x$, a word $\eta(s ; x)$ function of $s$ and $x$ only is printed on the output tape which is moved the corresponding length. Trivially, any mapping from $F_{X}$ to $F_{Y}$ can be performed by a transformation of this type if no restriction is imposed on the number of states. We shall always assume here that $S=$ $\{s\}$ is a finite set. This forces drastic limitations on $\eta$ and, in particular, it introduces a difference between the right transformations (where reading and printing are done from left to right) and the left transformations (where both operations are done in the opposite direction). For example no (finite) right automaton can perform the task of reproducing the input word when it ends with a given letter and of printing nothing when it does not.

Consequently the composite operation which consists of transforming first the input word by a right automaton, and then of transforming again the output word by a left automaton cannot as a rule be carried
out in a single pass; we shall call it a transduction and we shall describe some of its elementary properties:

1. The transductions form a set closed by finite composition and also by inversion when this last operation has a meaning (Huffman, 1959).
2. The transductions transform regular events (Kleene, 1956) on the input words into regular events on the output words and any regular event can be obtained in this manner.

These two properties indicate that there is no difference between the languages which can be accepted by finite automata and the languages which can be produced by any bounded number of finite automata; here, the boundedness condition cannot be omitted as is easily shown by Chomsky's counter examples (cf. Chomsky, 1959).

For notational reasons it is more convenient to define a transduction $\eta$ with sets of states ( $S, S^{\prime}$ ) as the transformation from an input word $f=x_{1} x_{2} \cdots x_{n}$ and a pair of states $s_{1} \varepsilon S, s_{1}^{\prime} \varepsilon S^{\prime}$ to an output word that is obtained by replacing every letter $x_{i}$ by a fixed output word $\eta\left(s_{i} ; x_{i} ; s_{n-i+1}^{\prime}\right)$ where the states are given inductively by the equations $s_{j+1}=s_{j} x_{j}$ and $s_{n-j+2}^{\prime}=x_{j} s_{n-j+1}^{\prime}$. With this definition, right (left) transductions correspond to the special case where $\eta\left(s_{i} ; x ; s_{i^{\prime}}^{\prime}\right)$ does not depend effectively upon its right (left) argument and where, consequently, $S^{\prime}(S)$ can be taken as reduced to a single state and, finally, omitted.

The finite closure property 1 shows that this new construct is equivalent to the composition of a right and of a left transduction; encodings correspond to the case where $S$ and $S^{\prime}$ reduce to a single state and, then, the property 1 shows that the deciphering can always be performed by a transduction.

Example. Let $X=\left\{x_{1}, x_{2}\right\}$ and $Y=\left\{x_{1}, x_{2}, y_{3}\right\}$. Every input word has a unique factorization $f=x_{i}^{n_{1}} x_{i^{\prime}}^{n_{2}} \cdots\left(i \neq i^{\prime}\right)$ into runs $x_{j}^{n_{k}}$ consisting of the same letter $x_{j}$ repeated $n_{k}$ times, and we suppose that we want to perform the transformation $\eta$ which lets invariant the runs of even length and replaces every run of odd length by $y_{3}$.

Thus, for example,

$$
\eta x_{1}^{3} x_{2}^{2} x_{1} x_{2}{ }^{3} x_{1}^{4}=y_{3} x_{2}{ }^{2} y_{3}{ }^{2} x_{1}{ }^{4}
$$

This can be realized if for any factorization $f=f^{\prime} x f^{\prime \prime}$ we follow the two instructions: (1) Print out $x$ if it belongs to a run of even length. (2) Print out $y_{3}$ or nothing when $x$ belongs to a run of odd length according to whether $x$ is or is not the last letter of this run.

In order to carry them out it is sufficient to know that $f^{\prime}$ and $f^{\prime \prime}$ respectively end and begin by runs of length $n^{\prime}>0$ and $n^{\prime \prime}>0$ in the letters $x^{\prime}$ and $x^{\prime \prime}$ because: (1) $x$ belongs to a run of even length if $x^{\prime}=$ $x=x^{\prime \prime}$ and $n^{\prime}$ and $n^{\prime \prime}$ have different parity or if $x^{\prime}=x \neq x^{\prime \prime}$ and $n^{\prime}$ is odd or if $x^{\prime} \neq x=x^{\prime \prime}$ and $n^{\prime \prime}$ is odd; (2) $x$ is the last letter of a run of odd length if $x \neq x^{\prime \prime}$ and $n^{\prime}$ is even, or if $x^{\prime} \neq x \neq x^{\prime \prime}$.

Consequently, all that is needed is the parity of $n^{\prime}$ and $n^{\prime \prime}$ and the last and first letter respectively of $f^{\prime}$ and $f^{\prime \prime}$. As we shall see below this information can be supplied by two finite state automata, one having read $f^{\prime}$ from left to right and the other one having read $f^{\prime \prime}$ in the opposite direction.

Let us now consider how this transformation could be achieved in two passes.

The first one is performed by a right transduction with states $\left\{s_{i}\right\}$ ( $0 \leqq i \leqq 4$ ), initial state $s_{0}$ and transitions:

$$
\begin{aligned}
& s_{0} x_{1}=s_{2} x_{1}=s_{3} x_{1}=s_{4} x_{1}=s_{1} \\
& s_{1} x_{1}=s_{2} \\
& s_{0} x_{2}=s_{1} x_{2}=s_{2} x_{2}=s_{4} x_{2}=s_{3} \\
& s_{3} x_{2}=s_{4}
\end{aligned}
$$

Thus for any input word $f^{\prime}$ the last state reached, $s_{j}$, has index of the same parity as the last run of $f^{\prime}$, and $j \leqq 2$ if and only if the last letter of $f^{\prime}$ is $x_{1}$. The machine has an output alphabet $Z=\left\{z_{i}\right\}(1 \leqq i \leqq 4)$ with the printing rule $\eta^{\prime}\left(s_{i} ; x_{j}\right)=z_{i^{\prime \prime}}$ when $s_{i} x_{j}=s_{i^{\prime}}$. For example,

$$
\eta^{\prime}\left(x_{1}^{3} x_{2}^{2} x_{1} x_{2}^{3} x_{1}^{4}\right)=z_{1} z_{2} z_{1} z_{3} z_{4} z_{1} z_{3} z_{4} z_{3} z_{1} z_{2} z_{1} z_{2}=\eta^{\prime} f .
$$

The second pass is performed by a left transducer with states $\left\{s_{i}\right\}$ ( $0 \leqq i \leqq 4$ ), initial state $s_{0}^{\prime}$ and transitions:
$z_{1} s_{i}{ }^{\prime}=s_{1}{ }^{\prime}$ if $i \neq 2$ and $z_{1} s_{2}{ }^{\prime}$

$$
=s_{2}^{\prime} ; z_{2} s_{i}^{\prime}=s_{2}^{\prime} \text { if } i \neq 1 \text { and } z_{2} s_{1}^{\prime}=s_{1}^{\prime} ;
$$

$z_{3} s_{i}{ }^{\prime}=s_{3}{ }^{\prime}$ if $i \neq 4$ and $z_{3} s_{4}{ }^{\prime}$

$$
=s_{4}^{\prime} ; z_{4} s_{i}^{\prime}=s_{4}^{\prime} \quad \text { if } \quad i \neq 3 \text { and } z_{4} s_{3}^{\prime}=s_{3}^{\prime} .
$$

The printing rule is given by $\eta^{\prime \prime}\left(z_{i} ; s_{j}^{\prime}\right)=x_{1} x_{1}$ when $i=2$ and $j \neq 1$; $=x_{2} x_{2}$ when $i=4$ and $j \neq 3 ;=y_{3}$ when $i=1$ and $j=0,2,4$ or $i=3$
and $j=0,1,2 ;=e_{Y}$ (nothing) in all other cases. For example,

$$
\eta^{\prime \prime}\left(\eta^{\prime} f\right)=e_{Y} e_{Y} y_{3} e_{Y} x_{2} x_{2} y_{3} e_{Y} e_{Y} y_{3} e_{Y} x_{1} x_{3} e_{Y} x_{1} x_{1}
$$

that is, $\eta\left(s_{0} ; f ; s_{0}{ }^{\prime}\right)$.

## II. FORMAL DEFINITION AND NERODE'S THEOREM

A transduction $\eta$ is given by the following structures:

1. A finite input alphabet $X=\{x\}$ and an output alphabet $Y=\{y\}$.
2. Two finite sets of states $S=\{s\}$ and $S^{\prime}=\left\{s^{\prime}\right\}$.
3. Two mappings $(S, X) \rightarrow S$ and $\left(X, S^{\prime}\right) \rightarrow S^{\prime}$ written respectively $s x$ and $x s^{\prime}$.
4. A mapping $\eta:\left(S, X, S^{\prime}\right) \rightarrow F_{Y}$ written $\eta\left(s ; x ; s^{\prime}\right)$. These mappings are extended in a natural fashion to any $f \varepsilon F_{X}$ by the following inductive rules:
$s e_{X}=s$ and $e_{X} s^{\prime}=s^{\prime}, \eta\left(s ; e_{X} ; s^{\prime}\right)=e_{Y}$ for any $\left(s, s^{\prime}\right) \varepsilon\left(S, S^{\prime}\right)$.
For any $f \varepsilon F_{X}, x \varepsilon X,\left(s, s^{\prime}\right) \varepsilon\left(S, S^{\prime}\right): s(f x)=(s f) x,(f x) s^{\prime}=$ $f\left(x s^{\prime}\right), \eta\left(s ; f x ; s^{\prime}\right)=\eta\left(s ; f ; x s^{\prime}\right) \eta\left(s f ; x ; s^{\prime}\right)$.

It is easily checked that these rules are equivalent to the ones given in the introduction. By induction the last rules gives the following identity which could be taken as a definition and which displays $\eta$ as a two-sided coset mapping $F_{X} \rightarrow F_{Y}$ : for any $f_{1}, f_{2}, f_{3} \varepsilon F_{X}$

$$
\eta\left(s ; f_{1} f_{2} f_{3} ; s^{\prime}\right)=\eta\left(s ; f_{1} ; f_{2} f_{3} s^{\prime}\right) \eta\left(s f_{1} ; f_{2} ; f_{3} s^{\prime}\right) \eta\left(s f_{1} f_{2} ; f_{3} ; s^{\prime}\right)
$$

In a more concrete manner $\eta$ can be realized by finite matrices whose entries belong to the umion of $F_{Y}$ and of a zero, 0 . Indeed for any $x \varepsilon X$ let $\mu x$ be a square matrix whose rows and columns are indexed by the pairs $\left(s_{i}, s_{i^{\prime}}^{\prime}\right) \varepsilon\left(S, S^{\prime}\right)$ and whose entries are

$$
\begin{aligned}
\mu x\left(\left(s_{i}, s_{i^{\prime}}^{\prime}\right),\left(s_{j}, s_{j^{\prime}}^{\prime}\right)\right) & =\eta\left(s_{i} ; x ; s_{j^{\prime}}^{\prime}\right) \quad \text { if } \quad s_{i} x=s_{j} \quad \text { and } \quad s_{i^{\prime}}^{\prime}=x s_{j^{\prime}}^{\prime}, \\
& =0, \text { otherwise. }
\end{aligned}
$$

Then if $f=x_{1} x_{2} \cdots x_{n}$ the corresponding output word $\eta\left(s ; f ; s^{\prime}\right)$ is equal to the entry $\mu f\left(\left(s, f s^{\prime}\right),\left(s f, s^{\prime}\right)\right)$ of $\mu f=\mu x_{1} \mu x_{2} \cdots \mu x_{n}$.

Proof. For any $f \varepsilon F_{X}$ and $x \varepsilon X$ we have

$$
\mu f x\left(\left(s_{i}, s_{i^{\prime}}^{\prime}\right),\left(s_{j}, s_{j^{\prime}}^{\prime}\right)\right)
$$

$$
=\Sigma\left[\mu f\left(\left(s_{i}, s_{i^{\prime}}^{\prime}\right),\left(s_{k}, s_{k^{\prime}}^{\prime}\right)\right)\right]\left[\mu x\left(\left(s_{k}, s_{k^{\prime}}^{\prime}\right),\left(s_{j}, s_{j}^{\prime}\right)\right)\right]
$$

where the summation is over all the pairs $\left(s_{k}, s_{k^{\prime}}^{\prime}\right) \varepsilon\left(S, S^{\prime}\right)$. The only
nonzero term in the sum is the one corresponding to the pair defined by the equations $s_{k}=s_{i} f$ and $s_{k^{\prime}}^{\prime}=x s_{j^{\prime}}^{\prime}$; we have then $s_{j}=s_{k} x$ and $s_{i^{\prime}}^{\prime}=$ $f s_{k^{\prime}}^{\prime}$, that is, $s_{j}=s_{i} f x$ and $s_{i^{\prime}}^{\prime}=f x s_{j^{\prime}}^{\prime}$. Thus the entry under consideration is equal to $\eta\left(s_{i} ; f ; x s_{j^{\prime}}^{\prime}\right) \eta\left(s_{i} f ; x ; s_{j^{\prime}}^{\prime}\right)$, that is, to $\eta\left(s_{i} ; f x ; s_{j^{\prime}}^{\prime}\right)$ and the result follows by induction.

Example. Let $X=\{a, b\} ; Y=\{c, d\} ; S=\left\{s_{1}, s_{2}\right\} ; S^{\prime}=\left\{t_{1}, t_{2}\right\} ;$ $s_{1} a=s_{2} a=s_{2} b=s_{1} ; s_{1} b=s_{2} ; b t_{1}=b t_{2}=a t_{2}=t_{1} ; a t_{1}=t_{2} \cdot \eta\left(s_{i} ; x ;\right.$ $t_{j}=c c$ if $x=a$ and $i=j$; $=d$ if $x=a$ and $i \neq j$ or if $x=b$ and $1=$ $i \neq j ;=c$ if $x=b$ and $i=j=2 ;=e_{Y}$ in all other cases.

Then, for instance, $\eta\left(s_{1} ; b b a b ; t_{1}\right)=c c c$ according to the following self-explanatory scheme

$$
\begin{array}{ccccc}
s_{1} & s_{2} & s_{1} & s_{1} & s_{1} \\
b\left(e_{Y}\right) & b(c) & a(c c) & s_{2} \\
t_{1} & t_{1} & t_{2} & t_{1} & t_{1}
\end{array} .
$$

Also we have
$\mu a=\left(\begin{array}{cccc}0 & d & 0 & 0 \\ c c & 0 & 0 & 0 \\ 0 & c c & 0 & 0 \\ d & 0 & 0 & 0\end{array}\right) ; \quad \mu b=\left(\begin{array}{cccc}0 & 0 & e_{Y} & d \\ 0 & 0 & 0 & 0 \\ e_{Y} & c & 0 & 0 \\ 0 & 0 & 0 & 0\end{array}\right) ; \quad \mu b b a b=\left(\begin{array}{cccc}0 & 0 & c c c & c c c d \\ 0 & 0 & 0 & 0 \\ 0 & 0 & d d & d d d \\ 0 & 0 & 0 & 0\end{array}\right)$
and $\eta\left(s_{1} ; b b a b ; t_{1}\right)$ is equal to $\mu b b a b\left(\left(s_{1}, t_{1}\right),\left(s_{2}, t_{1}\right)\right)$.
As an immediate consequence of the definitions we derive the following weak form of Nerode's ultimate periodicity theorem (Nerode, 1958). There exist finite integers $m$ and $n$ which are such that for any $f, f^{\prime}, f^{\prime \prime} \varepsilon F_{X}$, $\left(s, s^{\prime}\right) \varepsilon\left(S, S^{\prime}\right), p, r \geqq 0$, and $r \leqq n$ one has $\eta\left(s ; f^{\prime} f^{2 m+p n+r} f^{\prime \prime} ; s^{\prime}\right)=$ $g^{\prime} g^{p} g^{\prime \prime}$ where $g, g^{\prime}, g^{\prime \prime}$ \& $F_{Y}$ do not depend on $p$.

Proof. Since $S$ and $S^{\prime}$ are finite we can find integers $m$ and $n$ such that for all $\left(s, s^{\prime}\right) \varepsilon\left(S, S^{\prime}\right), f \varepsilon F_{X}, p \geqq 0,0 \leqq r \leqq n$, we have: $s f^{m+p n+r}$ $=s f^{m+r}, f^{m+p n+r} s^{\prime}=f^{m+r} s^{\prime}$. Thus

$$
\eta\left(s ; f^{\prime} f^{2 m+p n+1} f^{\prime \prime} ; s^{\prime}\right)
$$

$$
=\eta\left(s ; f^{\prime} f^{m+r} ; f^{p n+m f^{\prime \prime}} s^{\prime}\right) \eta\left(s f^{\prime} f^{m+r} ; f^{p n} ; f^{m} f^{\prime \prime} s^{\prime}\right) \eta\left(s f^{\prime} f^{m+p n+r} ; f^{m} f^{\prime \prime} ; s^{\prime}\right) .
$$

Because of our choice of $m$ and $n$ the second factor is equal to $p$ times the word $g=\eta\left(s f^{\prime} f^{m+r} ; f^{n} ; f^{m} f^{\prime \prime} s^{\prime}\right)$ and the result is proved.

## III. FINITE CLOSURE PROPERTIES

A. To any two transductions $\eta:\left(S ; F_{X} ; S^{\prime}\right) \rightarrow F_{Y}$ and $\xi:\left(T ; F_{Y} ; T^{\prime}\right)$ $\rightarrow F_{z}$ there corresponds a transduction $\pi:\left(R ; F_{x} ; R^{\prime}\right) \rightarrow F_{z}$ which is
such that for any $f \varepsilon F_{x},\left(s, s^{\prime}\right) \varepsilon\left(S, S^{\prime}\right),\left(t, t^{\prime}\right) \varepsilon\left(T, T^{\prime}\right)$ one has identically $\xi\left(t ; \eta\left(s ; f ; s^{\prime}\right) ; t^{\prime}\right)=\pi\left(r ; f ; r^{\prime}\right)$ where the states $r \varepsilon R$ and $r^{\prime} \varepsilon R^{\prime}$ are functions of $s$ and $t$ and of $s^{\prime}$ and $t^{\prime}$ respectively.

Proof. We define an equivalence relation $\sigma$ on $F_{X}$ by the following rules: $\sigma f=\sigma f^{\prime}$ (to be read: the $\sigma$-class of $f$ is the same as that of $f^{\prime}$ ) if and only if (1) for all $s \varepsilon S$, $s f=s f^{\prime}$; (2) for all $\left(s, s^{\prime}\right) \varepsilon\left(S, S^{\prime}\right)$ and $t \varepsilon T, t \eta\left(s ; f ; s^{\prime}\right)=\operatorname{t\eta }\left(s ; f^{\prime} ; s^{\prime}\right)$.
The relation $\sigma$ has at most $|S|^{|S|} \times|T|^{|T| \times|S| \times\left|s^{\prime}\right|}$ ( $|S|$ the number of states in $S$ ) distinct classes. Furthermore it is right regular (i.e., $\sigma f=\sigma f^{\prime}$ implies $\sigma f f^{\prime \prime}=\sigma f^{\prime} f^{\prime \prime}$ for all $f^{\prime \prime}$ ) since when $\sigma f=\sigma f^{\prime}$ we have (1) $s f f^{\prime \prime}=s f^{\prime} f^{\prime \prime}$ for any $s \in S$ (because $s f=s f^{\prime}$ ); (2) for any $\left(s, s^{\prime}\right) \varepsilon$ ( $S, S^{\prime}$ ) and $t \varepsilon T$,

$$
\begin{aligned}
\operatorname{t\eta }\left(s ; f f^{\prime \prime} ; s^{\prime}\right) & =\operatorname{t\eta }\left(s ; f ; f^{\prime \prime} s^{\prime}\right) \eta\left(s f ; f^{\prime \prime} ; s^{\prime}\right) \\
& =\operatorname{t\eta }\left(s ; f^{\prime} ; f^{\prime \prime} s^{\prime}\right) \eta\left(s f^{\prime} ; f^{\prime \prime} ; s^{\prime}\right)=\operatorname{t\eta }\left(s ; f^{\prime} f^{\prime \prime} ; s^{\prime}\right)
\end{aligned}
$$

We now define $R$ as the set of all triplets $r=(s, t, \sigma f)$ and the mapping $(R, X) \rightarrow R$ by $(s, t, \sigma f) x=(s, t, \sigma f x)$. In a perfectly symmetric manner we construct a left regular equivalence $\sigma^{\prime}$, a set of states $R^{\prime}=\left\{r^{\prime}\right\}=$ $\left\{\left(s^{\prime}, t^{\prime}, \sigma^{\prime} f\right)\right\}$, and a mapping $\left(X, R^{\prime}\right) \rightarrow R^{\prime}$. Finally, we put $\pi\left((s, t, \sigma f) ; x ;\left(s^{\prime} ; t^{\prime} ; \sigma^{\prime} f^{\prime}\right)\right)$

$$
=\xi\left(t \eta\left(s ; f ; x f^{\prime} s^{\prime}\right) ; \eta\left(s f ; x ; f^{\prime} s^{\prime}\right) ; \eta\left(s f x ; f^{\prime} ; s^{\prime}\right) t^{\prime}\right)
$$

This definition is free from ambiguity because the three expressions $\eta\left(\quad ; \quad ; \quad\right.$ ) entering in it depend only upon the classes $\sigma f$ and $\sigma^{\prime} f^{\prime}$; this is a direct consequence of the definition of $\sigma$ and $\sigma^{\prime}$ and it concludes the proof since it is sufficient now to check by developing the expressions that if $f=f^{\prime} x f^{\prime \prime}$ we have $\xi\left(t ; \eta\left(s ; f ; s^{\prime}\right) ; t^{\prime}\right)=\pi\left(r ; f ; r^{\prime}\right)$ where $r=$ ( $s, t, \sigma e_{X}$ ) and $r^{\prime}=\left(s^{\prime}, t^{\prime}, \sigma^{\prime} e_{X}\right)$. Before verifying the second closure properties we recall the following facts:

1. Let $R_{z}$ denote the family of the subsets $F^{\prime} \subset F_{z}$ that are regular events in the sense of Kleene (1956). The specification of an $F^{\prime} \varepsilon R_{Z}$ is equivalent (cf. Shepherdson, 1959) to that of an homomorphism $\gamma$ : $F_{Z} \rightarrow P$ where $P$ is a finite monoid together with the subset $P^{\prime}$ of $P$ associated to $F^{\prime}$ by the relations $\gamma F^{\prime}=P^{\prime} ; F^{\prime}=\gamma^{-1} P^{\prime}\left(=\left\{f: \gamma f \varepsilon P^{\prime}\right\}\right)$. The equivalence on $F_{Z}$ defined by $\gamma f=\gamma f^{\prime}$ is at the same time left and right regular and it has only finitely many classes.
2. According to D. Huffman's theory (1959) the transformation $\eta$ can
be said to be information lossless on the subset $F^{\prime}$ of $F_{X}$ if the equations $\eta\left(s ; f ; s^{\prime}\right)=\eta\left(s ; f^{\prime} ; s^{\prime}\right) ; s f=s f^{\prime} ; f s^{\prime}=f^{\prime} s^{\prime} ; f, f^{\prime} \varepsilon F^{\prime}$ imply $f=f^{\prime}$.
B. If $\eta$ is information lossless on the subset $F^{\prime} \varepsilon R_{X}$ there exists a transduction $\xi\left(=\eta^{-1}\right)$ which is such that for any $f \varepsilon F^{\prime},\left(s, s^{\prime}\right) \varepsilon\left(S, S^{\prime}\right)$ we have $\xi\left(t ; \eta\left(s ; f ; s^{\prime}\right) ; t^{\prime}\right)=f$ where the states $t \varepsilon T$ and $t^{\prime} \varepsilon T^{\prime}$ are functions of $s$ and $f s^{\prime}$ and of $s^{\prime}$ and $s f$ respectively.

Proof. Let $H$ be the set of all the words $\eta\left(s ; x ; s^{\prime}\right)$ with $x \in X$ and $K\left(K^{\prime}\right)$ the set of all proper right (left) factors of the words of $H$ (i.e., $k \varepsilon K$ if and only if $k f \varepsilon H$ for some $f \neq e_{Y}$ ). If $\sigma$ is a right regular equivalence on $F_{X}$ with $|\sigma|$ classes, we say that $g \varepsilon F_{Y}$ admits a factorization of type ( $\sigma f, s_{i}, s_{j^{\prime}}^{\prime}, s_{j}, s_{i^{\prime}}^{\prime}, k$ ) (where $\sigma f$ is any $\sigma$-class; $s_{i}, s_{j} \varepsilon S ; s_{i^{\prime}}^{\prime}$, $s_{j^{\prime}}^{\prime} \varepsilon S^{\prime} ; k \varepsilon K$ ) if there exist $f^{\prime} \varepsilon F_{X}$ and $g^{\prime} \varepsilon F_{Y}$ such that the following relations are satisfied:
$\sigma f=\sigma f^{\prime} ; \quad g=g^{\prime} k ; \quad g^{\prime}=\eta\left(s_{i} ; f^{\prime} ; s_{s^{\prime}}^{\prime}\right) ; \quad s_{i} f^{\prime}=s_{j} ; \quad f^{\prime} s_{i^{\prime}}^{\prime}=s_{j}^{\prime}$.
Clearly, if $h \mid$ is the maximal length of an element of $H$, there exist at most $|\sigma| \times\left(|S| \times\left|S^{\prime}\right|\right)^{2} \times|h|$ different types of factorization. Thus if we write $\lambda g_{1}=\lambda g_{2}$ when the elements $g_{1}, g_{2} \varepsilon F_{Y}$ admit exactly the same set of types of factorization, the relation $\lambda$ has only a finite number of classes when the same is true of $\sigma$ and, by construction, $\lambda$ is right regular. In perfectly symmetric manner we associate a left regular equivalence $\lambda^{\prime}$ on $F_{Y}$ to any left regular $\sigma^{\prime}$ on $F_{X}$.

We now come to the construction of $\xi$. As indicated above we construct the relations $\lambda$ and $\lambda^{\prime}$ on $F_{Y}$ associated with the (left and right regular) relation $\gamma$ on $F_{X}$ used for the definition of $F^{\prime}$, and we define $T$ as the set of all triples $\left(s, s^{\prime}, \lambda g\right)$ with $\left(s, s^{\prime}\right) \varepsilon\left(S, S^{\prime}\right)$ and $\lambda g$ a $\lambda$-class; the mapping $(T, Y) \rightarrow T$ is given by $\left(s, s^{\prime}, \lambda g\right) y=\left(s, s^{\prime}, \lambda g y\right)$. The set of states $T^{\prime}$ and the mapping $\left(Y, T^{\prime}\right) \rightarrow T^{\prime}$ are defined in symmetric manner with the help of the relation $\lambda^{\prime}$.

For each triple $\left(s, s^{\prime}, x \varepsilon X\right)$ such that $\eta\left(s ; x ; s^{\prime}\right) \neq e_{Y}$ we select arbitrarily one factorization $k y k^{\prime}$ of $\eta\left(s ; x ; s^{\prime}\right)$ and we define $\xi$ by the following rules: $\xi\left(\left(s_{1}, s_{4}{ }^{\prime}, \lambda g\right) ; y ;\left(s_{4}, s_{1}{ }^{\prime}, \lambda^{\prime} g^{\prime}\right)\right)=x$ if there exists $\bar{g}, \bar{g}^{\prime} \varepsilon F_{Y}$; $k \varepsilon K ; k^{\prime} \varepsilon K^{\prime} ; f, f^{\prime} \varepsilon F_{X} ; s_{2}, s_{3} \varepsilon S ; s_{2}^{\prime}, s_{3}^{\prime} \varepsilon S^{\prime}$ satisfying the following relations:

$$
\begin{aligned}
& \lambda g=\lambda \bar{g} k ; \lambda^{\prime} g^{\prime}=\lambda^{\prime} k^{\prime} \bar{g}^{\prime} ; \\
& \bar{g}=\eta\left(s_{1} ; f ; s_{3}^{\prime}\right) ; s_{1} f=s_{2} ; f_{s_{3}}{ }^{\prime}=s_{4}^{\prime} ; s_{2} x=s_{3} \\
& \bar{g}^{\prime}=\eta\left(s_{3} ; f^{\prime} ; s_{1}^{\prime}\right) ; s_{3} f=s_{4} ; f^{\prime} s_{1}^{\prime}=s_{2}^{\prime} ; x s_{2}^{\prime}=s_{3}^{\prime}
\end{aligned}
$$

$k y k^{\prime}$ is the selected factorization of $\eta\left(s_{2} ; x ; s_{3}{ }^{\prime}\right)$;
$f x f^{\prime}$ belongs to $F^{\prime}$.
In all other cases the value of $\xi\left(\quad\right.$ ) above is $e_{Y}$.
The possibility of solving all except the last of the above equations for given $y \varepsilon Y, \lambda g, \lambda^{\prime} g^{\prime}, s_{1}, s_{4}, s_{1}{ }^{\prime}, s_{4}{ }^{\prime}$ is a direct consequence of the definition of $\lambda$ and $\lambda^{\prime}$. Taken together these equations imply that there exists at least one triple $f, x, f^{\prime} \varepsilon F_{X}$ for which $\eta\left(s_{1} ; f x f^{\prime} ; s_{1}^{\prime}\right)=\bar{g} k y k^{\prime} \bar{g}^{\prime}=g^{\prime \prime}$ with a selected factorization; $s_{1} f x f^{\prime}=s_{4}$ and $f x f^{\prime} s_{1}{ }^{\prime}=s_{4}{ }^{\prime} ; f x f^{\prime} \varepsilon F^{\prime}$.

Thus, if the word $g^{\prime \prime}=\overline{\bar{g}} k y k^{\prime} \overline{\bar{g}}^{\prime}$ has been obtained from a word $f^{\prime \prime}$ in $F^{\prime}$ by a transduction with the indicated initial and final states, it follows from Section III, A that $\xi\left(t ; g^{\prime \prime} ; t^{\prime}\right)$ will be identical to $f^{\prime \prime}$ and, because of the hypothesis that $\eta$ is information lossless on $F^{\prime}$, this proves a posteriori that the above equations have a unique solution.

Remark.
Because of the assumption that $S^{\prime}$ is finite it is always possible to realize in a single pass any arbitrary transduction if one is allowed to use a bounded number of output tapes and if one has the possibility of erasing on them.

Since the general case is rather cumbersome it may be sufficient to restrict ourselves to the detailed examination of the procedure needed for the deciphering of an encoding. Thus, let us assume now that $S$ and $S^{\prime}$ are reduced to a single element and that consequently $\eta$ is an isomorphism $F_{X} \rightarrow F_{Y}$. The sets $H$ and $K$ have the same meaning as in Section III, B and $P=\eta F_{X}$ is the submonoid of $F_{Y}$ generated by $H$.

To any $g \varepsilon F_{Y}$ we associate the set $\lambda g$ of those $k \varepsilon K$ which are such that $g=p k$ for some $p \varepsilon P ; \lambda g$ contains at most $|h|$ elements and, consequently, the equivalence relation on $F_{Y}$ defined by $\lambda g=\lambda g^{\prime}$ has only finitely many classes; since, furthermore, it is right regular we can construct a conventional automaton whose states are identified with the various possible $\lambda g$ 's and whose transitions are given by ( $\lambda g) y=\lambda(g y)$. We still observe that for any $g \varepsilon F_{Y}$ either $\lambda g$ is empty (and in this case $g$ cannot be a left factor of a word in $P$ ) or, if $k \varepsilon \lambda g$ there exists a uniquely determined element $f=\xi p \varepsilon F_{X}$ such that $g=(\eta f) k=p k$.

Let us now consider a word $g^{\prime \prime} \varepsilon P$ and any factorization $g^{\prime \prime}=g y g^{\prime}$ of it; let us assume also that we have been able to record on $|\lambda g|$ tapes the words $\xi p_{i}$ corresponding to the $|\lambda g|$ elements $k_{i} \varepsilon \lambda g$. The automaton is in state $\lambda g$ and upon reading the letter $y$ it will go to the state $\lambda(g y)$.

For each $k_{i} \varepsilon \lambda g$ four cases are possible and we list below the printing instructions to be followed in each of them:

1. $k_{i} y$ does not belong to $H$ nor to $K$ (i.e., $k_{i} y$ cannot be a left factor of a word of $P$ ); then the machine erases the corresponding word $\xi p_{i}$.
2. $k_{i} y$ belongs to $H$ and not to $K$; the machine writes on the corresponding tape the letter $x \varepsilon X$ such that $\eta x=k_{i} y$; thus, on this tape we now have $\left(\xi p_{i}\right) x$.
3. $k_{i} y$ belongs to $K$ and not to $H$; the machine does nothing on the corresponding tape.
4. $k_{i} y$ belongs to $H$ and to $K$; the machine does as in 2 above but also it takes a new tape and it reproduces on it the word $\xi p_{i}$. This new tape corresponds to the element $k_{i} y \varepsilon \lambda(g y)$ and the old tape corresponds to the element $e_{Y} \varepsilon \lambda(g y)$.

At the end of the reading of $g^{\prime \prime}, \lambda g^{\prime \prime}$ contains $e_{Y}$ because, by hypothesis, $g^{\prime \prime} \varepsilon P$ and the corresponding tape carries the word $\xi g^{\prime \prime}$ such that $\eta\left(\xi g^{\prime \prime}\right)$ $=g^{\prime \prime}$. It is clear that, at any given stage of the procedure $|h|$ tapes, at most, are needed since we can use the tapes made free by the operation 1 above.

The proof of the validity of the algorithm is left to the reader and in Tables I and II we give a complete account of the construction of the state diagram and of the deciphering of the word $a^{4} b a^{4} b^{2} a^{2}$ for the following example:

$$
\begin{gathered}
X=\left\{x_{i}\right\}(1 \leqq i \leqq 5) ; \quad Y=\{a, b\} ; \\
\eta x_{1}=a a ; \quad \eta x_{2}=b a a ; \quad \eta x_{3}=b b ; \quad \eta x_{4}=b a ; \quad \eta x_{5}=b b \\
K=\left\{e_{Y}, a, b, b a, b b\right\}
\end{gathered}
$$

(This is an encoding because it is a left prefix code in the three words: $u=a ; v=b a ; w=b b$ ) (Schützenberger, 1956). We find $\xi\left(a^{4} b a^{4} b^{2} a^{4}\right)=$ $x_{1}^{2} x_{2} x_{1} x_{3} x_{1}$.

## IV. RELATIONSHIP WITH REGULAR EVENTS

As we shall deal here with fixed initial states, we write for any subset $F^{\prime}\left(G^{\prime}\right)$ of $F_{X}\left(F_{Y}\right)$ :

$$
\begin{aligned}
& \eta F^{\prime}=\left\{g \varepsilon F_{Y}: g=\eta\left(s_{1} ; f ; s_{1}^{\prime}\right), f \varepsilon F^{\prime}\right\} ; \\
& \eta^{-1} G^{\prime}=\left\{f \varepsilon F_{\Sigma}: \eta\left(s_{1} ; f ; s_{1}^{\prime}\right) \varepsilon G^{\prime}\right\} .
\end{aligned}
$$

A. The subset $G^{\prime}$ of $\eta F_{X}$ belongs to $R_{Y}$ if and only if $\eta^{-1} G^{\prime}$ belongs to $R_{X}$.

TABLE I

| K | $e_{Y}$ | $a$ | $b$ | $b a$ | $b b$ | Corresponding states and transitions |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $e_{Y}$ | + |  |  |  |  | $t_{1}$ |
| $a$ |  | + |  |  |  | $t_{2}=t_{1} a$ |
| $b$ |  |  | $+$ |  |  | $t_{3}=t_{1} b$ |
| $a a$ | + |  |  |  |  | $t_{1}=t_{2} a$ |
| $a b$ |  |  |  |  |  | $t_{0}=t_{1} b=t_{n} a=t_{0} b$ |
| $b a$ |  |  |  | $+$ |  | $t_{4}=t_{3} a$ |
| $b b$ | $+$ |  |  |  | $+$ | $t_{5}=t_{3} b$ |
| $b a a$ | + | $+$ |  |  |  | $t_{6}=t_{4} a$ |
| $b a b$ |  |  | + |  |  | $t_{3}=t_{4} b$ |
| $b b a$ | + | $+$ |  |  |  | $t_{6}=t_{5} a$ |
| $b b b$ |  |  | $+$ |  |  | $t_{3}=t_{5} b$ |
| baaa | $+$ | $+$ |  |  |  | $t_{6}=t_{6} a$ |
| $b a a b$ |  |  | $+$ |  |  | $t_{3}=t_{6} b$ |

Proof. By definition there corresponds to every $F^{\prime} \varepsilon R_{X}$ a right regular equivalence $\gamma$ with finitely many classes such that $F^{\prime}$ is a union of $\gamma$ classes; in the proof of Section III, B we have seen how to construct $\lambda$ associated to $\gamma$ and such that $\eta F^{\prime}$ is a union of $\lambda$-classes; since $\lambda$ is right regular and has only finitely many classes, this proves the forward implication. In particular, since $F_{X}$ belongs to $R_{X}$, this shows that the total output $\eta F_{x}$ is a regular event.

Now let $G^{\prime}$ be a subset of $\eta F_{X}$ that belongs to $R_{Y} ; G^{\prime}$ is defined by a certain right regular relation $\lambda$ with finitely many classes and we construct the relation $\sigma$ on $F_{X}$ by the following conditions:
$\sigma f=\sigma f^{\prime}$ if and only if (1) $s_{1} f=s_{1} f^{\prime}$; (2) for any $s^{\prime} \varepsilon S^{\prime}, \lambda \eta\left(s_{1} ; f ; s^{\prime}\right)=$ $\lambda \eta\left(s_{1} ; f^{\prime} ; s^{\prime}\right) . \sigma$ is right regular because, if $\sigma f=\sigma f^{\prime}$, we have $s_{1} f f^{\prime \prime}=$ $s_{1} f^{\prime} f^{\prime \prime}$ and $\lambda \eta\left(s_{1} ; f f^{\prime \prime} ; s^{\prime}\right)=\left(\lambda \eta\left(s_{1} ; f ; f^{\prime \prime} s^{\prime}\right)\right) \eta\left(s_{1} f ; f^{\prime \prime} ; s^{\prime}\right)=$ $\left(\lambda \eta\left(s_{1} ; f^{\prime} ; f^{\prime \prime} s^{\prime}\right)\right) \eta\left(s_{1} f^{\prime} ; f^{\prime \prime} ; s^{\prime}\right)=\lambda \eta\left(s_{1} ; f^{\prime} f^{\prime \prime} ; s^{\prime}\right)$ where the second and third equality result from the right regularity of $\lambda$ and where the second equality is a consequence of $\sigma f=\sigma f^{\prime}$. Also, $\sigma$ has at most $|S| \times|\lambda|^{\left|s^{\prime}\right|}$ classes and $\eta^{-1} G^{\prime}$ is a union of $\sigma$-classes. This concludes the proof.
B. Provided that $X$ contains two letters or more, there corresponds to each $G^{\prime \prime} \varepsilon R_{Y}$ a right transduction $\eta$ such that $G^{\prime \prime}=\eta F_{X}$.

Proof. Because of our hypothesis on $X$ it is sufficient to prove the same statement for an arbitrarily large (finite) input alphabet and then to perform a preliminary encoding.

The result is trivial if $G^{\prime \prime}$ is finite and, by Kleene's theory, it is sufficient to show that if $G$ and $G^{\prime}$ are the total outputs respectively of the right transductions $\eta$ and $\eta^{\prime}$ (with the disjoint input alphabets $X$ and $X^{\prime}$ ) we can construct right transductions $\eta_{1}, \eta_{2}, \eta_{3}$ (with input alphabet $X \cup X^{\prime}$ ) such that their total output is respectively $G \cup G^{\prime}, G G^{\prime}$, and $G^{*}$ in Kleene's notation. The construction given below is the simplest to describe.

Let $S$ and $S^{\prime}$ be the set of states of the right transducers $\eta$ and $\eta^{\prime}$; we can assume that $S$ and $S^{\prime}$ are disjoint and we define $S^{\prime \prime}$ as the union of $S, S^{\prime}$ and of two new states $s_{1}^{*}$ and $s_{0}{ }^{*}$ for which we have:

TABLE II

1. $s_{1}{ }^{*} x^{\prime \prime}=s_{1} x^{\prime \prime}$ or $=s_{1}^{\prime} x^{\prime \prime}$ and $\eta_{i}\left(s_{1}^{*} ; x^{\prime \prime}\right)=\eta\left(s_{1} ; x^{\prime \prime}\right)$ or $=\eta^{\prime}\left(s_{1}^{\prime} ; x^{\prime \prime}\right)$ according to $x^{\prime \prime} \varepsilon X$ or $\varepsilon X^{\prime}$.
2. $s_{0}{ }^{*} x^{\prime \prime}=s_{0}{ }^{*}$ for all $x^{\prime \prime}$ and $\eta_{i}\left(s^{\prime \prime} ; x^{\prime \prime}\right)=e_{Y}$ for all $s^{\prime \prime}, x^{\prime \prime}$ such that $s^{\prime \prime} x^{\prime \prime}=s_{0}{ }^{*}$.
3. $s^{\prime \prime} x^{\prime \prime}$ and $\eta_{i}\left(s^{\prime \prime} ; x^{\prime \prime}\right)$ are the same as in the original transducers when $s^{\prime \prime} \varepsilon S$ and $x^{\prime \prime} \varepsilon X$ or when $s^{\prime \prime} \varepsilon S^{\prime}$ and $x^{\prime \prime} \varepsilon X^{\prime}$.
4. $\eta_{1}: s^{\prime \prime} x^{\prime \prime}=s_{0}^{*}$ when $s^{\prime \prime} \varepsilon S$ and $x^{\prime \prime} \varepsilon X^{\prime}$ or when $s^{\prime \prime} \varepsilon S$ and $x^{\prime \prime} \varepsilon X$. For $\eta_{2}: s^{\prime \prime} x^{\prime \prime}=s_{1} x^{\prime \prime}$ and $\eta_{2}\left(s^{\prime \prime} ; x^{\prime \prime}\right)=\eta_{2}\left(s_{1}^{*} ; x^{\prime \prime}\right)$ when $s^{\prime \prime} \varepsilon S^{\prime}$ and $x^{\prime \prime} \varepsilon X^{\prime}$ and $s^{\prime \prime} x^{\prime \prime}=s_{0}^{*}$ when $s^{\prime \prime} \varepsilon S^{\prime}$ and $x^{\prime \prime} \varepsilon X$. For $\eta_{3}$, we take $G=G^{\prime}$ (and $S$ identical to $S^{\prime}$ ) and we define $s^{\prime \prime} x^{\prime \prime}=s_{1}^{*}$ and $\eta_{3}\left(s^{\prime \prime} ; x^{\prime \prime}\right)=$ $\eta_{3}\left(s_{1}^{*} ; x^{\prime \prime}\right)$ when $s^{\prime \prime} \varepsilon S$ and $x \varepsilon X^{\prime}$ or when $s^{\prime \prime} \varepsilon S^{\prime}$ and $x^{\prime \prime} \varepsilon X$.

The verification is left to the reader.
