Analitical approach to neuromarketing as a business strategy

Asela A. Burgos-Campero*, José G. Vargas-Hernandez

University of Guadalajara (U de G) Periferico Norte 799 Edif. G201-7, México

Abstract

The aim of this paper is to analyze the theoretical and methodological approaches to the study of neuromarketing for designing business strategies. The initial question is based on incorporating advances in neuro-marketing to the field of strategic direction. The research method used is to review the literature to study this phenomenon. The main conclusion is that neuro-marketing allows us to know the customer's reactions in terms of brain activation without the need to appeal to the report of his conscious experience. In consequence the firms will be able to develop capacities and valuable resources to create focal strategies.

Keywords: Business strategy, capacities and resources, neuro-marketing,

1. Introduction

If neuroscience is seen in its childhood, neuro-marketing is clearly in an embryonic state. Marketing academics just wake up to the possibility offered to reveal the brain circuits involved in the search, selection and purchase of a product (Morin, 2011).

While the economy has begun using neuro-imaging techniques in its research that has resulted in neuroeconomics marketing has shown leery at the idea of expanding their research using new techniques, even though both fields share common interests, such as decision making and exchange (Lee, Broderick and Chamberlain, 2007). Neuro-marketing is an emerging interdisciplinary field that combines psychology,

neuroscience and economics (Lee et. al., 2007) whose term has been coined by Smidts in 2002 (Lewis and Bridger, 2005)

While neuroscience has grown dramatically in the last decade, it has not penetrated easily into the academy of marketing mainly because very few researchers have formal training in cognitive neuroscience, and the fear produced by public criticism about of the ethical issues involved in the use of neuro-imaging (Morin, 2011). This ethical debate, despite being in a lot of articles has not been explicit in Mexican universities, including a large number of scholars and students know basics of neuroscience despite working directly with the search, satisfaction and needs assessment of consumer.

The brain is responsible for all consumer behaviours. Despite being only 2% of the body mass, it is using a large amount of energy, approximately 20% of our total energy. Most of the functions you need are handled by the brain at an unconscious level. This account to explain why for almost 80% of the cerebral energy is required to maintain the baseline status. Clearly, it is used only 20% of the brain consciously (Morin, 2011). So it is disturbing that despite this information, companies continue applying methodologies based on the reports articulated of their clients, jeopardizing their investments and waste the vast amount spent each year on brain studies.

Braidot (2005) states that the needs describe what people need to live. These needs become wants when the customer thinks about a product or service to satisfy demand and when you have the purchasing power to buy at the point of sale. The study of customer needs is at the heart of the concerns of the organizations as the key to staying competitive lies in the ability to identify and develop products and services that can satisfy them better than competitors. Both needs and wished involve the biological and social human beings, although ultimately is preferable to separate for study.

While the way language is used can vary from culture to culture, the language of the brain maintains stability in the results. The goal of neuro-marketing is to study the physiological response of the brain to advertising and marketing strategies. In order to evaluate the effectiveness of these strategies, the resulting brain activity from this phenomenon is monitored and measured using neuro-imaging techniques. Neuroscientists are now able to directly study the frequency, location and timing of neuronal activity in an unprecedented way. However, marketing has ignored these developments and their potential (Lee, et al., 2007).

So the aim of this study is to show an overview of the advances in neuroscience and how they have helped broaden the knowledge of those who from their niche continue asking questions about human behavior. The research has benefited from the ongoing global multidisciplinary input, but does not seem to attract enough attention at home, leaving out the possibility of providing local information to supplement neuro.scientific studies with the cultural characteristics of each social group

2. Difficulties of the traditional methods of marketing.

Marketing scholars have considered a few years ago that market research was accurate and credible sample that allowed organizations to make informed business decisions. However as reported by Pradeep (2005, 5) 80% of the failures of new products in the market, the economic cost implied provides strong evidence of the difficulties faced.

Although each year are invested over 40 billion dollars in advertising campaigns, conventional methods to try and predict the effectiveness of this investment shows flaws because it depends on the willingness and capability of the client to describe how he/she feels when is exposed to advertising (Morin, 2011). The failure is due primarily to the fact that people assume they are able to describe their own cognitive processes, which, it is well known now, the cognitive processes have many subconscious components.

The methods of "articulated answers" as market research, surveys and focus groups to name some of them, are not ideal to know the way a person feels about a product or service because it is difficult to describe in precise words the emotions experienced by a person to a stimulus such as a product. Braidot (2005) considers that researchers would be trying to ask the conscious mind what their unconscious mind recorded to translate into language that accurately reflect the phenomenon. Neuroscience has reported in turn that the brain alters the original response recorded as the accessing process to translate the information stored in a physical response that carries said alteration.

In the case of focus groups participants' responses may be influenced by the dominant group subjects, in addition to factors such as incentives, time and pressure that may have some interference in its report. Surveys in turn require substantial samples and design tools developed to be able to counter variables such as language, education and culture between subjects tested (Pradeep, 2010, 10).

3. Contemporary neuro-scientific methodologies.

As it has been observed, traditional methodology is unable to replicate or model what the brain does, how it operates and what it perceives around itself (Pradeep, 2010, 9). In contrast, Neurological tests reach a rigorous degree of scientific and actionable results for various reasons. First, it requires smaller samples and that despite the differences that we find between the brain of a man and a woman, and, between a children compared to an adult, our brains are much more alike than different (Pradeep, 2010, 11).

Second, neuro-scientific methodologies provide insight through neuro-imaging, brain areas involved and subconscious processes without conscious effort of the participants. Third, it offers the possibility to study in real time, allowing the viewer to understand the phenomena related to specific times of the test. Fourth, most of these methods measure the physiological response noninvasively. However, each has certain limitations which will be discussed below.

The EEG is an acronym of the Electro encephalography. Hans Berger designed the first practical application of EEG in 1920 (Pradeep, 2010, 3). This passive technology uses sensors to pick up electrical signals due to activation of brain waves (Pradeep, 2010, 11). To do this, it uses a cap with electrodes that are placed on the head of each participant of the study to measure low voltage signals.

When a stimulus is presented to a subject, such as a television commercial, neurons produce a small electrical current that can be amplified. This electric power has multiple frequency patterns, called brain waves, which are associated with different states of consciousness. Brain waves can be recorded in small time intervals, some EEG can record up to 10,000 times per second, which is very valuable because of the speed with which information is acquired through the senses and speed of our thoughts. It is estimated that about 80% of our brain activity is used to maintain a state of rest or baseline so it cannot be assumed that the brain waves generated are entirely produced by a stimulus (Morin, 2011).

The EEG has become the best instrument to evaluate the wave brain handles cognitive information along providing subjacent information about neural mechanisms (Pereyra, 2011, 26). The EEG is also a very sensitive device to measure low voltage signals so before the assessment is carried out a search of the subject's brain activity to create a baseline and reduce noise. Some limitations of EEG are that no shows a good enough spatial resolution to localize precisely the place where a neuron produces electricity, especially in the deeper and older structures of the brain (Morin, 2011).

Morin (2011) refers to previous studies such as those carried out by Reeves Lang, Forson and Rothschild (1989) to record activation in the left frontal lobe related to positive messages of television scenes using only four electrodes, while today, this system may be use 256 electrodes to monitor brain activity. This does not mean that early research was inaccurate but emphasizes the speed with which this field has evolved in a few years.

Functional magnetic resonance imaging (FMRI) is a tool that uses an MRI scanner to observe in an image changes in brain blood flow. The study participant lies on a narrow tube while registering firing neurons to stimuli presented. Neurons need to use energy, which is carried by the bloodstream and rapidly metabolized. The key element to marketing research is to understand the contrast of the signals in the dependent level of oxygenated blood (BOLD). To a stimulus some brain areas of the subject receive more oxygenated blood than they had received in a previous time (Morin, 2011).

This change creates a distortion in the magnetic field emitted by the hydrogen protons in water molecules in the blood. The basis of FMRI studies is to consider that a change in the BOLD signal is an accurate measure of neural activity, with a spatial resolution ten times better than the EEG. The limitations of this instrument has to do with a delay of about five seconds which is the time between which it is produced the brain activation and BOLD signal changes, and the high cost of equipment (Pradeep, 2010, 13).

Magneto encephalography (MEG) emerged in the mid-60's records the magnetic fields of the brain and that brain activity is a function of electrochemical signals between neurons. This neuronal activity creates magnetic fields that can be amplified and mapped using MEG which has an excellent temporal resolution as well as a better spatial resolution than the EEG. Morin (2011) believes that one of its limitations is that not a good method to observe sub cortical areas as best recorded brain activity of the cortex. This suggests that the best way is to use MEG to measure activity in known areas or which are expected to be produced in a specific task, rather than used for exploratory experiments.

The eye tracking device displays the products or advertisements on a sensitive screen to the sight and look, which allows determining what people see every millisecond in real time. The results show the areas that the participating persons observed for longer period of time and the path of the eye movements. This technique can be used together with the EEG for further evaluation. Currently the company Tobii has designed lenses that function as eye trackers recording what attracts the attention of the individual to be analyzed in their software, which allows researchers to make an accurate study in real-time and contexts.

4. First steps towards an interdisciplinary work.

Despite the great potential, the applications of neuro-imaging in relation to marketing initially focused primarily on brands and consumer behaviour, particularly using EEG to explore people's reactions. Also it was used to assess individual preferences between the brand familiarity and preference for the product, comparing familiar vs. no familiar brands. When consumers see a brand for the first time feels a negative uncertainty compared with one familiar already to him, which through repetition of advertising messages at low levels increases effectiveness and reduces uncertainty. Advertisers should be aware that repeated exposure to excess damages their advertising because it causes boredom in the consumer, must be balanced to be recognized by the customer and avoid over exposure of a product (Madan, 2010).

With current advances, it might be able even to know by eye tracking aspects that attract the customer's attention and what appears to be a distraction in the form of offering a product, obtaining a more detailed report that achieves to fill any gaps in the phenomena studied previously.

5. Interdisciplinary work: The phenomena in terms of brain activation

The collaboration between neuroscience and marketing can expand the knowledge in important areas, from the expected questions such as the relationship between the consumer and the product, the influence of advertising stimuli, the formation of a brand, unmet needs and business opportunities, to the interaction

of organizations in specific market contexts and identification of emotions in terms of brain activation, undoubtedly enriching themes for contemporary society.

Important aspects such as trust have been explored by neuro-marketing. To research this aspect at organizational level is very important because it can be designed better strategic alliances, joint ventures, mergers and / or acquisitions. To Motterlini (2008) trust is a determining factor for both parties. Without genuine trust, any party runs the risk of opportunistic behavior.

Marketing research has conceptualized trust as something more than a behavior of rational economic calculation. Apparently neuros-cientific methods can provide information on trust development. Early studies have linked activation of the caudate nucleus with this phenomenon (Lee et al., 2007). But this is only the beginning of a fine and detailed research that will correspond to future research.

The psychology of pricing on its part has been investigated in order to know the effects on the consumer price. Despite the amount of literature available, companies seem to use very little of this information when setting their prices at a disadvantage getting (Lee, et al., 2007). Recent studies have explored the mistakes made by consumers when they process terminated prices 0.99 compared with integers, suggesting that the individual pays less attention to the last sequence numbers. Others have investigated the social role of the same in terms of brain activation (Lee, et al., 2007). It appears that commodity prices are influenced by emotional based rewards. Knowing the price of a product as salt price compared to the price of a sports car shows brain activation in areas other than suggesting a different processing of the same.

Studies made in real time have allowed the parties to linking the parts to the most important processes related to marketing. Madan (2010) has reported that the medial prefrontal cortex (mPFC) is a repository of links between factual knowledge and bio-regulatory states. This translates to product information linked to positive affect pathway (mPFC); an increase in activation (mPFC) and superior frontal gyrus marks when there are observed family marks, which can improve its projection rapidly if gain consumer confidence through the use of celebrities.

Regarding sub cortical areas most frequently involved in neuro-marketing research Madan (2010) cited the amygdale, responsible among other things for emotional processing of information and the intensity of the reward. The ventral striatum, including the nucleus acumens, and the brain's reward center, are another indicator of predictive reward and hippocampus relative to the memory involved in the recognition of brands, products and services.

6. The neuro-marketing as business strategy

The strategy concept may have different views. In this paper it is defined the strategy as the alignment or direction of the resources available to an organization in terms of changes in their environment (Vargas, 2012) and it also focus on the strategy as the theory of a firm about how compete successfully (Peng, 2010, 10). Also the core of the concept is related to the formulation of the strategy and the implementation thereof. That is why the neurosciences in conjunction with cognitive science, psychology and marketing have gone into the business arena by providing new ways to observe and analyze consumer behavior and how it makes decisions.

Knowing these techniques provides businesses a useful tool for obtaining more accurate information to create strategies and competitive advantages that lead to a better positioning in the market; this is where the neuro-marketing becomes relevant. For example, it is well known that companies focus on well-defined market segments and use their resources to outline strategies that can meet the needs and expectations of its clients and their potential clients in highly competitive environments. However, marketing executives and advertising so far have based their predictions on intuition, experience and articulated consumer reports to try to predict whether advertising is effective.

As far as basing predictions of what neuroscientists already know about how humans process information and respond to various stimuli can lead to make decisions with greater confidence (Lee, Butler and Senior, 2010). By understanding more scientific and specific the various types of customers, inquiring about their cognitive and perceptual characteristics to apply this knowledge to satisfy their needs and wants is one of the major interests of neuro-marketing (Braidot, 2005, 210). Therefore, neuro-marketing can help companies to strategize more focused and less uncertainty.

The resource-based view suggests that the specific capabilities of a firm lead to the difference in performance. The winning firms have valuable skills, unique and difficult to imitate (Peng, 2010:16). So as more objective information which offers neuro-marketing provides insight into customer needs to enable organizations to better ability to innovate, develop and refine their marketing strategies. While most research analyzes how the brain perceives reality and focus on sensory processing of information, currently is being analyzed numerous experiments that reveal how it affects the image of the brand in those preferences (Braidot, 2005, 216). Unlike conventional advertisers that work with preconceived ideas about the success of an announcement, it should be fun and the design must be conspicuous (Gladwell, 2000, 105).

Most of the time, human beings are making decisions, whether consciously or unconsciously, they are choosing between numerous alternatives presented at a given time and based on available information. Knowing these aspects where reason and emotion are together in deciding possible by combining conventional marketing techniques in collaboration with the opportunities provided by neuro-scientific methodologies. When entering into the literature on this topic, it is realized that the human being is less rational than it has been seen before and maybe there is nothing wrong with this. From ancient Greece the Descartes's ideas have been very effective, considering a separation between reason and emotion. Plato even longed for the chance to get rid of what he called "Horses of emotion" to make better decisions, although neuro-scientific studies have questioned these ideas.

The case of a successful lawyer Elliot who after undergoing surgery to remove a tumor of the frontal lobe began displaying behaviors which seemed not to be aware of their emotions despite maintaining their cognitive abilities intact. Because along with his brain tumor removed from their prefrontal lobes, cutting the connections between the lower centers of the emotional brain, this made him able to take all the steps prior to decision making, but unable to assign values to different options (Damasio, 1994, 55-72.)

This case would have been fascinated precisely to Plato, although it has been precisely contradicted, the emotions seem to have a relevant role in decision making. The interaction between cortical and sub cortical areas in this process realizes the continuous negotiation between automatic and controlled processes. Dragolea and Cotîrlea (2011) mention that the neurologist Donald Caine believed that the essential difference between emotion and reason is the fact that emotions make us act while reasoning only allows us to assess.

Making a decision requires comprehensive knowledge and rational strategies to operate on this knowledge. The reasoning processes occur around options for action, predicting future results and plans for implementing various goals in varying scales of time. The images with which a person reasons when thinking must be active in working memory and the customer should keep in mind all possible options and strategies to buy (Braidot, 2005, 103).

One of the most famous studies that account for some of the topics that were discussed previously is performed by McClure, Li, Tomlin, Cypert, Montague and Montague (2004b) about the preference between two soft drink brands which reported a higher preference for Coca-Cola versus Pepsi and related activation emotions and affections (ventromedial prefrontal cortex) when participants were informed that they were taking the Coca-cola. However, the blind test showed no contrary evidence. The interesting

thing about this study is not the choice between the two lines, but the evaluation of the two decisions before the decision itself.

Gladwell (2005, 185-186) argues that the difficulties of interpretation of the study between Pepsi and Coca-Cola are based on the fact that they are based on what professionals call sip tasting, in which the tasters do not drink the whole can but take a sip, which is something very different from drinking altogether. In a tasting sip, consumers prefer the taste sweeter while the entire can take that same sweetness becomes cloying. The Pepsi is sweeter than Coke, which gives it a huge advantage in a tasting sip. This is a wonderful example of the difficulty of finding out what people really think so to take advantage of the assessments made by consumers of cola, before they have to decide which of these two reactions they want more.

So it is a case where it can be inferred that the neurosciences in conjunction with existing methodologies mentioned above can provide companies a solid foundation to create or recreate their positioning strategies. This study reinforces the complexity of decision making and the importance of emotions, situational aspects and information resources available to the consumer. This research does not provide the neural code of decisions but shows the potential power of such studies. These data have been confirmed by studying with people who had suffered damage to the prefrontal cortex (Madan, 2010). Despite having provided information that was consuming the brand, it has showed no difference in their preferences as in the case study (McClure et al., 2004a) in participants without brain damage.

Despite their usefulness neuro-marketing is not limited to use of neuro-imaging techniques, complemented by neuroscience and cognitive science to be able to quantify the behavioral processes. Madan (2010) takes the form in which decisions can be divided into five steps: (a) identify the problem before which a decision is made, (b) assess the possible choices, (c) make the decision based on the evaluation of the available options, (d) consider the resulting consequences, and (e) learn from this process to make better decisions in the future. Viewed this way it is easier to analyze why free will is an unconstructive way of conceptualizing how humans choose.

7. Cultural aspects in consumer behavior

Studies of preferences for a product show that culture values some aspects which may act as a secondary gain related to a primary need. People learn to meet their needs in different ways according to their socioeconomic and cultural profile. They develop different subjective habits, conditioned by their own neural wiring, personality, age and the influences they receive from their environment (Braidot, 2005). Erk, Spitzer, Wunderlich, Galley, & Walter (2002) found that objects with high social value representation (sports cars) had resulted in increased activation in reward centers (orbit frontal cortex, anterior cingulated region and occipital cortex) compared with lower social value objects (small cars).

In this same line many companies undertake communication campaigns to achieve desirable social goals, as to persuade young people not to drink, not to smoke, not to pollute the environment, among others. These campaigns besides showing a behavior consistent with the values of society, they also underpin a corporate image with long-term benefits (Braidot, 2005). The association of the brand with these behaviors carries a code that gives consumers a strong group membership based on the ideology of the same and therefore strengthens their affective bond.

Local studies allow more objective comparisons on these premises, Iyengar (2010 p. 56-57) reported behavioral studies of choice that show marked differences between East and West.

8. The ethical aspects: Looking for restrictions or regulations?

Ethical issues have been the central debate about neuro-marketing studies. It is relatively easy to find literature that argues against these studies as Nature Neuroscience editorial published in 2004 that the only interest of neuro-marketing is to find what they call the "Buy button" to create advertising campaigns that we will not be able to resist. The main fear of consumer protection groups focuses on the vulnerability of people to the application of this information in its mysterious review that can lead to specific neurological effects intentionally.

However, ethical issues have not been addressed only to marketing but also to communications, sociology, politics and psychology. The effects of advertising, according to Morin (2011) can contribute to society beyond simply finding the "Buy bottom ". The application of neuroscience can provide a basis of understanding of how humans create, store, recall and relate information as it does with a mark in their daily lives. It would also be possible to discover whether some aspects of marketing activities trigger negative effects such as consumerism. In fact, the field of neuro-marketing should be considered a legitimate and important area that allows understanding human behavior in extremely important business relationships.

Ethics should not be a stranger field to any professional as it relates to society in general. Adina Roskies defines neuro-ethics research as the research on how to deal with social issues of disease, normality, mortality, lifestyle and philosophy of life in the light of understanding of the brain mechanisms that underlie all these issues (Bonete 2010, 70).

Neuro-imaging studies have even suggested that neural activity precedes conscious intention questioning free will, especially if this can be monitored by an external observer (Madan, 2010). However the potential restriction of free will and the possible invasion of privacy require the evaluation of academic and government regulation, consumers should know who is collecting this data and the potential uses of the information (Wilson, Gaines and Hill, 2008).

9. Conclusions

Undoubtedly obtaining information from the neuro-marketing is more accurate because it takes into account not only the sociological and psychological profiles of customers, but also the cognitive. Thus, neuroscience gives us the ability to explore more of each group and segment the market on more solid bases (Braidot, 2005, 217).

Studies using neuro-imaging methodologies provide insight into real-time consumer response to a specific stimulus. The image of a brand can arouse emotions that can be more powerful than the effect of the product itself. In other words a strong brand image alters perception towards the product (Dragolea et al., 2011). Hence, the importance of knowing the underlying processes of customers in ways that enterprises develop valuable skills and resources to generate targeted strategies.

The neuro-marketing provides a real competitive advantage in an increasingly saturated market (Pradeep, 2010, 5). Unfortunately the outdated and insufficient input from alumni and students in the country has implications that disadvantage the business growth and undermine the opportunity to compete in international markets. This lack of local research results in a small body of information to be compared with studies done in other countries and cultural aspects that could differentiate consumer behavior.

So the heart of the interaction between neuroscience and business is not using one method but in the way how to address business problems. So it is very likely to have a neuro-scientific approach in marketing research, in significant organizational problems and decisions will give a better understanding of why human beings behave generally or react the way they do and they will be in a better position to more accurately predict this (Lee, et al., 2010).
