Background: The impact of percutaneous coronary intervention (PCI) for chronic total occlusion (CTO) in patients with smoking history is not clear. Smoking history is known to have an adverse effect on clinical outcomes of coronary artery diseases. We evaluated the 12-month clinical outcomes between PCI and optimal medical therapy (OMT) for CTO lesions in patients with smoking history.

Methods: A total of 321 consecutive CTO patients with smoking history were divided into 2 groups according to treatment strategy; PCI group (n=145) and OMT group (n=176). Twelve-month clinical outcomes were retrospectively compared between the two groups.

Results: At baseline, patients in the OMT group had a lower left ventricular ejection fraction, and higher prevalence of elderly, cerebrovascular accident, peripheral vascular disease, congestive heart failure, left main disease, multivessel disease, right coronary artery CTO lesion, and collaterals & grade 2. Clinical outcomes at 12 months were similar between the 2 groups except lower mortality in the PCI group at univariate analysis. After baseline adjustment by multivariate analysis, 12-month mortality remained lower in the PCI group (OR 0.112, 95% CI 0.014-0.910, p=0.041) despite of increased target lesion revascularization (TLR) in the PCI group (table).

Conclusion: In our study, PCI seems to be a favorable choice of therapy for CTO lesions in patients with smoking history.

Background: There have been many studies regarding acetylcholine (Ach) induced coronary artery spasm (CAS). However, although spastic coronary artery at baseline coronary angiography is common in clinical practice, clinical outcomes according to the response to Ach in patients with basal CAS are unknown.

Methods: A total of 728 patients without significant coronary lesion who had spastic coronary angiogram at baseline before Ach test during angiography procedure were enrolled. National Cholesterol Education Program Adult Treatment Panel III (NCEP-ATP III) was used for the definition of Metabolic Syndrome (MS). The pts were divided into two groups; MS group (n=385, 60.1%) and non-MS group (n=2810, 39.9%). Ach provocation test was performed by incremental dosage (20 μg, 50, 100μg) into left coronary artery. Significant CAS was defined more than 70% luminal narrowing visually with chest pain with/without ST segment changes.

Results: Baseline characteristics were balanced between the two groups except the MS group had more elderly, hypertension, diabetes, dyslipidemia, and cerebrovascular accident, whereas the male gender, peripheral vascular disease, current smoking and alcohol were lower in the MS group. Angiography characteristics during Ach provocation test, the MS group showed higher incidence of QCA measured severe CAS, mean % narrowing and smaller mean diameter than non-MS group (Table).

Conclusion: According to our study, the MS pts had more coronary risk factors and worse angiographic characteristics during Ach provocation test, suggesting more careful medical therapy and follow up would be required.

Background: Metabolic Syndrome (MS) has been known to be an important cardiovascular risk factor. We investigated whether the presence of MS can impact on coronary artery spasm (CAS) as assessed with intracoronary acetylcholine (Ach) provocation test.

Methods: A total 3490 consecutive patients (pts) who underwent coronary angiography with Ach provocation test were enrolled. National Cholesterol Education Program Adult Treatment Panel III (NCEP-ATP III) was used for the definition of the MS. The pts were divided into two groups; MS group (n=680, 19.5%) and non-MS group (n=2810, 80.5%) groups. Ach provocation test was performed by incremental dosage (20 μg, 50, 100μg) into left coronary artery. Significant CAS was defined more than 70% luminal narrowing visually with chest pain with/without ST segment changes.

Results: Baseline characteristics were balanced between the two groups except the MS group had more elderly, hypertension, diabetes, dyslipidemia, and cerebrovascular accident, whereas the male gender, peripheral vascular disease, current smoking and alcohol were lower in the MS group. Angiography characteristics during Ach provocation test, the MS group showed higher incidence of QCA measured severe CAS, mean % narrowing and smaller mean diameter than non-MS group (Table).

Conclusion: According to our study, the MS pts had more coronary risk factors and worse angiographic characteristics during Ach provocation test, suggesting more careful medical therapy and follow up would be required.
