**Methods**

We examined the apnoea hypopnea index (AHI) using polygraphy (PG) in 60 consecutive patients with ACS who underwent coronary angiography. OSA was defined by AHI≥5 events per hour and was considered severe if the AHI≥30 events per hour. The Friesinger score was calculated for each patient from the coronary angiography to evaluate the severity of CAD.

**Results**

The average age of patients was 59.73 years±10.1 years. The sex ratio was 1.5.

61.7% of patients had an AHI≥5 and 21.7% had severe OSA with AHI≥30. The Friesinger score was significantly greater in the group with multivessel CAD (11, 28±4, 17 versus 5, 35±3, 96, p=0.0001). There were no differences between patients having multivessel CAD and those with single-vessel CAD regarding clinical characteristics.

Table summarizes these results.

**Conclusion**

In summary, these data suggest a high occurrence of obstructive sleep apnoea in patients with CAD, which should be taken into account when considering risk factors for CAD. However, severe OSA is not more frequent in the group of multivessel CAD. Further studies are needed to evaluate the impact of the presence of severe OSA on short and long term prognosis.

**Introduction**

Pulmonary veins (PV) play a crucial role in triggering and generating atrial fibrillation (AF). Isolation of PVs is fundamental in the AF ablation whether paroxysmal or persistent. The presence of four distinct pulmonary veins (two left PVs and two right PVs) has been described as the normal variant.

**Aim**

The purpose of our study was to investigate whether the age of the patients had an influence on the incidence of anatomical abnormalities of PVs.

**Methods**

Our study was a prospective study which has included 38 patients followed for AF in the cardiology’s department of our hospital. All patients underwent a CT scan of PVs in order to characterize their anatomy. PVs’ size was represented by the largest diameter. We have divided our cohort into two groups: group 1: patients aged more than 50 years and group 2: patients aged less than 50 years.

**Results**

Our patients had a mean age of 50.5±13 years. The majority of our patients had paroxysmal AF (65%), 4 had persistent AF (10%), 9 had prolonged persistent AF (25%).

CT Scan of PV results according to age are summarized in table.

**Conclusion**

In our study, we found no significant relationship between age and anatomical abnormalities of the PVs. Hence, it is important to look for these anatomical anomalies whatever was the age of the patients to increase the success rate and to avoid complications during the AF ablation procedures.

**Introduction**

Obstructive sleep apnoea (OSA) is associated with oxidative stress, risk factors including hypertension, and with binary presence of coronary artery disease (CAD). However, whether OSA contributes to the severity of CAD and to future adverse events in patients with CAD remains unknown.

**Aim**

The aim of this study was to investigate the association between severe OSA and multivessel CAD.

**Table**

Atrial fibrillation after radiofrequency ablation of atrial flutter: prevalence and risk factors

Mathias Guinot’, François Lesaffre, Pierre Nazeyrollas, Karine Bauley, Jean-Pierre Chabert, Leila Simone, Huu Tri Bui, Anthony Foulon, Bertrand Girodet, Julien Voyez, Damien Metz

_CHU Reims, Reims, France_

*Corresponding author: mathias_guinot@orange.fr (Mathias Guinot)

**Background**

Radiofrequency ablation (RFA) is the only curative treatment for typical atrial flutter (AFL) and allows stopping antiarrhythmic drugs. However, atrial fibrillation (AF) is frequent during follow-up but predictive factors of AF onset are unknown while it is necessary to diagnose it in order to apply the correct antithrombotic strategy.

**Aims**

To determine prevalence and predictors of AF after AFL RFAAFL.
