Calix[4]arene; Aldimine; Iminecalix[4]arenes microwave-assisted synthesis; Antifungal activity; X-ray crystal structure; Pinched cone conformation

Abstract In this study, six iminecalix[4]arenes were synthesized and the crystal structures of two of the iminecalix[4]arenes were also determined. Iminecalix[4]arene adopts a strongly pinched cone conformation with two upper rim substituents pointing toward and the other two pointing away from the aromatic cavity. This uncommon conformation is stabilized by an intramolecular π...π interaction between the phenyl rings from the upper rim substituents pointing inwards the cone. In addition, phenyl rings from the substituent groups are not coplanar with respect to the calixarene phenyl rings holding them. The compounds, as well as their respective monomeric units, were evaluated for their antifungal activities against Candida strains. All the synthesized iminecalix[4]arenes were found to cause higher inhibition of all tested Candida strains than their respective monomers. The ratio between the minimal inhibitory concentration (MIC) of a monomer and the corresponding iminecalix[4]arene ranged from 2.05 to 36.50. Furthermore, the iminecalix[4]arene bearing nitrofuran group exhibited low MIC values comparable to that of fluconazole. Thus, this compound was twice more active than fluconazole against Candida krusei.

1. Introduction

In the last few decades, calixarenes and their functionalized derivatives have attracted increasing attention due to their technological and biological applications (Consoli et al., 2006, 2011; Motornaya et al., 2006; Mourer et al., 2010, 2012; Patel et al., 2012; Ukhatskaya et al., 2013; Pelizzaro-Rocha et al., 2013), particularly as platforms for the development of new drugs (de Fátima et al., 2009; Varejão et al., 2013; Lappchen et al., 2015; Tauran et al., 2015; Giuliani et al., 2015). The
highly organized structures of the calixarenes could give rise to interesting synergistic effects that are not observed in their respective monomeric units. In this sense, studies conducted in 2007 by Grare and coworkers indicate that a p-guanidinoethylcalix[4]arene shows broad spectrum antibacterial activity, while no antibacterial activity was observed with the corresponding monomer guanidinoethylphenol (Grare et al., 2007). Two years later, the same group reported that other three p-guanidinoethylcalix[4]arenes also possess, in general, better antibacterial activities than their corresponding monomers (Mourer et al., 2009). Characteristics such as easy-to-perform in multi-gram applications in medicinal chemistry (Krˇenek et al., 2007; Deshayes and Gref, 2014; Guo and Liu, 2014; Kamboh et al., 2014; Du et al., 2015).

Fungi have remained neglected pathogens in terms of drug discovery (Sundriyal et al., 2006; Choi et al., 2014) despite their highlighted clinical relevance (Andriole et al., 1999; Ascuioglu et al., 2002; Nucci et al., 2005; Franco-Paredes et al., 2015). The Candida species are certainly the most important opportunistic fungal pathogens for humans (Pfaller et al., 2006; Pfaller and Diekema, 2007; Whibley and Gaffen, 2015). Candidiasis may range from non-life threatening mucocutaneous illnesses to invasive processes (Pappas et al., 2004; Sparber and LeibundGut-Landmann, 2015). Both mucosal and deep tissue infections are mainly caused by C. albicans (Pappas et al., 2004). Candida species other than albicans have been assumed to be the pathogens of nosocomial infections in immunocompromised patients (Walsh et al., 1995; Girmenia et al., 1996; Whibley and Gaffen, 2015). Concerning the currently available antifungal drugs, most active compounds exhibit drawbacks, such as fungi resistance, toxicity, limited efficacy, and high cost (Sundriyal et al., 2006; Rizi et al., 2015). This scenario clearly indicates that research on new antifungal agents is required.

Aldimines are known to exhibit remarkable biological properties (Abdallah et al., 2010; da Silva et al., 2011a; Sztanke et al., 2013; Matar et al., 2015; Ammerkar et al., 2015; Hisaindee et al., 2015). Recently, our research group demonstrated that aldimes show interesting inhibitory activity against a variety of pathogenic fungi, including Candida, Aspergillus, and Cryptococcus species (da Silva et al., 2011b; Magalhães et al., 2013; Gasparoto et al., 2015). Calixarenes have also demonstrated antifungal profiles (Paquet et al., 2006; Patel et al., 2012; de Oliveira et al., 2012). In this context, the synthesis of hybrid calixarene–aldimines presents a promising strategy for obtaining new compounds with enhanced antifungal activity. Calixarene-based aldimes have been successfully synthesized previously as precursors of anion receptor in water (Klimentová and Vojtíšek, 2007). We here report the microwave-assisted synthesis of six iminecalix[4]arenes (compounds 6–11; Scheme 1) and their respective monomeric units (compounds 14–19; Scheme 2). Crystal structures of two of the synthesized compounds were determined. The antifungal activities against six species of Candida are also described.

2. Experimental

2.1. Chemistry

2.1.1. General procedures

All chemicals were obtained from commercially available sources and used without further purification. Melting points (uncorrected) were determined on Mettler FP 80 HT apparatus. Infrared spectra were recorded on a Perkin Elmer Spectrum One spectrophotometer (ATR). 1H and 13C NMR spectra were recorded on a Bruker AVANCE DPX-200 spectrometer or a VARIAN MERCURY-300 spectrometer in CDCl3. High-resolution mass spectra were recorded on a Shimadzu LCMS-IT-TOF instrument. Compounds 5 and 13 (Schemes 1 and 2) were synthesized according to procedures reported in the literature (Li et al., 2009, 2011).

Well-shaped single crystals of compounds 7 and 10 (Schemes 1 and 2) with dimensions of 0.32 × 0.21 × 0.05 mm3 and 0.25 × 0.012 × 0.05 mm3 were exposed to the X-ray beam (Mo Kα or Cu Kα radiation from μS microsources with multilayer optics) at room temperature using a Bruker-AXS Kappa Duo diffractometer equipped with an APEX II CCD detector. The diffraction frames were recorded by φ and ω scans using APEX2 (Bruker, 2012), and this software package was also employed for treatment of the raw dataset. The structures were solved using direct methods of phase retrieval with SHELXS-97 (Sheldrick, 2008). Identification of C, O, and N atoms was done directly from the Fourier synthesis maps, which were then refined with
anisotropic atomic displacement parameters (ADPs). All refinements were performed using the full-matrix least squares method on $F^2$ using SHELXL-97 (Sheldrick, 2008). Hydrogen atoms were stereochemically positioned with fixed individual isotropic ADPs based on the equivalent isotropic ADP of the parent non-hydrogen atom ($U_{iso}(H) = 1.2 \times U_{eq}$ or 1.5 $U_{iso}(H)$ in C atoms and a $U_{iso}(H)$ in methyl groups), or 1.2 $U_{eq}$ in methyl groups and a $U_{iso}(H)$ in phenyl groups). The MERCURY (Macrae et al., 2008) and ORTEP-3 (Farrugia, 2012) programs accessed through the WinGX software package were used to prepare structure illustrations. CCDC reference numbers 1439308 and 1439309 contain the crystal data for compounds 7 and 10, respectively.

Additionally, a positional disorder in the upper rim substituent at calixarene phenyl rings 2 and 4 was found in the case of compound 7 and was refined using the classical split-atom approach. Two sets of atomic sites were found for each substituent. Their major occupancies were constrained to 55% and 60% for the substituents at phenyl rings 2 and 4, respectively. The minor occupancy factors were constrained to 45% and 40%, and their labels followed those from major ones but ended with apostrophe.

Crystal data for compound 7. C$_{72}$H$_{77}$N$_{4}$O$_{12}$. MW = 1125.37, monoclinic, $a = 12.405(5)$ Å, $b = 30.137(12)$ Å, $c = 17.782$ (7) Å, $\beta = 101.502(9)^\circ$, $V = 6514(4)$ Å$^3$, $T = 297(2)$ K, space group P2$_1$/c, $Z = 4$, $D_c = 1.148$ g cm$^{-3}$, $\mu$ (Mo K$\alpha$) = 0.075 mm$^{-1}$, $\beta$-range for data collection = 1.35–25.49, $14 \leq h \leq 15$, $-36 \leq k \leq 33$, $-9 \leq l \leq 21$, 53392 reflections collected, 11865 unique ($R_{int} = 0.0706$), 4797 with $I > 2\sigma(I)$, completeness to $\theta_{max} = 97.9\%$, $F_{000} = 2400$, 918 parameters refined, $S = 1.145$, $R(I > 2\sigma(I)) = 0.126$.

Crystal data for compound 10. C$_{72}$H$_{77}$N$_{4}$O$_{12}$. MW = 1237.41, monoclinic, $a = 13.713(4)$ Å, $b = 28.956(9)$ Å, $c = 17.592(6)$ Å, $\beta = 103.184(18)^\circ$, $V = 6801(4)$ Å$^3$, $T = 297(2)$ K, space group P2$_1$/c, $Z = 4$, $D_c = 1.209$ g cm$^{-3}$, $\mu$ (Mo K$\alpha$) = 0.082 mm$^{-1}$, $\beta$-range for data collection = 1.68–25.45, $-16 \leq h \leq 16$, $-34 \leq k \leq 34$, $-21 \leq l \leq 19$, 70533 reflections collected, 12361 unique ($R_{int} = 0.0685$), 6191 with $I > 2\sigma(I)$, completeness to $\theta_{max} = 98.2\%$, $F_{000} = 2624$, 833 parameters refined, $S = 1.084$, $R(I > 2\sigma(I)) = 0.086$, $wR_2$(all data) = 0.2574, largest diff. peak/hole = 0.360/–0.321 e Å$^{-3}$.

Unit cell data for compound 11. monoclinic, $a = 14.793(3)$ Å, $b = 33.55(9)$ Å, $c = 13.41(3)$ Å, $\beta = 100.68(8)^\circ$, $V = 6539 (27) Å^3$, $T = 297(2)$ K, $\beta$-range for data collection (Cu K$\alpha$) = 7.22–42.04, $-10 \leq h \leq 9$, $-24 \leq k \leq 27$, $-7 \leq l \leq 11$, 3083 reflections collected, 2684 unique ($R_{int} = 0.0479$), 1241 with $I > 2\sigma(I)$.

Compound 5 (0.15 mmol) and respective aldehydes (0.66 mmol, 1.1 equivalents for amino group) were solubilized in ethanol (20 mL). The mixtures were irradiated in a Discover CEM® reactor for 20 min at reflux temperature. After the reaction was complete, the products were isolated by filtration.

(−)-N-(4-butoxyphenyl)-1-(5-nitrofuran-2-yl)methanimine (19)

Yield: 85%. Yellow solid. Mp: 137.8–139.3 °C. IR (ATR, cm⁻¹): 3144, 2936, 2863, 1619, 1576, 1531, 1498, 1394, 1336, 1293, 1239, 1181, 1115, 1041, 1025, 1011, 838, 815, 739. ¹H NMR (200 MHz, CDCl₃): δ 0.98 (t, 3H, J₈₋₇ = 7.2 Hz, H₈), 1.50 (sex, 2H, J₇₋₆ = J₇₋₈ = 7.2 Hz, H₇), 1.78 (quin, 2H, J₆₋₅ = J₆₋₇ = 7.2 Hz, H₆), 3.99 (t, 2H, J₅₋₆ = J₅₋₇ = 7.2 Hz, H₅), 6.93 (d, 2H, J₂₋₃ = 7.6 Hz, H₂), 7.14 (s, 1H, H₁₄), 7.30 (d, 2H, J₃₋₂ = 7.6 Hz, H₃), 7.41 (s, 1H, H₁₂).
Synthesis, crystal structures, and anticandidal activity of iminecalix[4]arenes

2. Antifungal activity

2.2.1. Microorganisms

Candida albicans ATCC 18804, Candida krusei ATCC 20298, Candida tropicalis ATCC 750, Candida parapsilosis ATCC 22019, Candida glabrata ATCC 90030 and Candida dubliniensis CBS 7987 were procured from the American Type Culture Collection (Manassas, VA). All strains were maintained in the Laboratory of Mycology of the Institute of Biological Sciences at Federal University of Minas Gerais, MG, Brazil, on slopes of Sabouraud dextrose agar (SDA, Difco, Detroit MI, USA) or potato dextrose agar (PDA, Difco) and subcultured every two months.

2.2.2. Susceptibility assay

The antifungal susceptibility test was performed by a broth microdilution assay according to CLSI guidelines M27-A2 (CLSI, 2002). The test compounds were dissolved in dimethyl-sulfoxide (DMSO) and further diluted with sodium bicarbonate-free RPMI-1640 medium (INLAB, Diadema, SP, Brazil) buffered with 165 mM morpholine propanesulfonic acid (MOPS, Sigma), pH 7.0, supplemented with 4 mM 1-glutamine. Each compound was tested in 10 serial concentrations (2048–4.0 µg mL⁻¹). From each dilution, 100 µL was dispensed into flat-bottom 96-well micro titration plates (Cral, Cotia, SP, Brazil). Fluconazole (Sigma-Aldrich, Co, MO, USA) was used as positive control. In addition, growth and sterility control wells were included for each isolate tested. Fungal species were cultured on SDA for 48 h. Concentrations of the fungal inoculums were adjusted spectrophotometrically. Appropriate dilutions were performed using RPMI-1640 medium to obtain a two-fold test inoculum concentration (1 to 5 × 10⁵ cells mL⁻¹). All assays were done in duplicate on at least three different occasions. Inoculum suspensions and solutions of test compounds were mixed (1:1) in sterile flat-bottom 96-well microplates (Difco Laboratories, Detroit, MI, USA). Growth, sterility and toxicity control wells were included for each isolate tested. Microplates were incubated at 35 °C and minimum inhibitory concentration (MIC) endpoints for each microorganism were established at the end of the incubation. MIC values for test compounds corresponded to the lowest concentration necessary to completely inhibit (visually) fungal growth while MIC values for fluconazole were determined as the lowest concentration necessary to inhibit fungal growth by 50%.

3. Results and discussion

3.1. Synthesis of compounds 6–11 and 14–19

Iminecalix[4]arenes 6–11 were prepared according to the synthetic approach shown in Scheme 1. Initially, the p-tert-butylcalix[4]arene (1) was synthesized from the condensation reaction between p-tert-butylphenol and formaldehyde, in the presence of sodium hydroxide (Gutsche et al., 1990). Dealkylation of 1 with aluminum chloride and phenol led to compound 2 with 80% yield (Gutsche and Lin, 1986), which was then treated with 1-bromobutane and sodium hydride leading to ether 3 (Nomura et al., 2010). Nitration and subsequent reduction reactions led to intermediate 5 with a yield of 53% (from 3) (Li et al., 2009; Sansone et al., 2006). Finally, the condensation of 5 with different aromatic aldehydes, assisted by microwave irradiation, resulted in iminecalix[4]arenes 6–11 in moderate to good yields. The structural features of the derivatives of the calixarenes were determined from the corresponding IR, 1H NMR, 13C NMR and mass spectroscopy data.

The main absorption bands in IR spectra of compounds 6–11 were recorded in the region of 1600 cm⁻¹, corresponding to the stretching of C=O and C≡N bonds, common to all the compounds. The 1H NMR spectra showed one pair of doublets for methylene bridges at δ ~ 3.25 and ~4.50 ppm, that are characteristics of cone conformation adopted by macrocycles. Singlets of the imino protons (–CH=N–) were observed at δ 7.92–8.28 ppm. For the 13C NMR spectra, the signals for the imino carbons were observed at δ ~ 142.2–161.0 ppm.

The aldimines 14–19, corresponding to respective monomeric units of iminecalix[4]arenes 6–11, were synthesized in a similar manner (Scheme 2). Treatment of 4-nitrophenol with 1-bromobutane and sodium carbonate furnished the compound 12 that was reduced to give the amine 13. The condensation of 13 with different aromatic aldehydes, assisted by microwave irradiation, provides aldimines 14–19 with good yields.

3.2. X-ray crystal structures of iminecalix[4]arenes 7 and 10

Compounds 7 and 10 have been crystallized in the monoclinic space group P2₁/c with one molecule in the asymmetric unit and therefore four ones within their unit cell. Their crystal are very similar, including similar cell constants and volume besides equal lattice symmetry (see crystal data in Experimental section). An illustration of the asymmetric units of compounds 7 and 10 showing the labeling scheme of phenyl rings from the calixarene base, from one to four (C1 to C6, C8 to C13, C15 to C20, and C22 to C27, in this order), is shown in Figs. 1 and 2. Their crystallographically independent molecule adopts a strongly pinched cone conformation with two upper rim substituents pointing inwards and the other two pointing outwards from the aromatic cavity. This uncommon conformation is driven by an intramolecular π...π interaction between the phenyl rings from the upper rim substituents attached to phenyl rings 1 and 3. These two phenyl rings from either ortho-hydroxylphenyl in 7 or benzoxazole in 10 are practically parallel, with a small angle between them of 15.3(5)° in 7 or 0.8(17)° in 10, besides exhibiting a staggered disposition with a separation between their centroids of 3.912(11) Å in 7 or 3.525(10) Å in 10. These are relatively short separations supporting the occurrence of the π...π interaction aforementioned. The occurrence of this interaction driving the pinched cone conformation has been already reported in related iminecalix[4]arenes with four propyl groups at the lower rim and 3-pyridyl, 2-thienyl or 2-pyrrolyl as substituents in lieu of substituted phenyl rings in 7 and 10 (Klimentová and Vojtíšek, 2007) as well as in calix[4]arenes with perfluorophenyl ring directly bonded to calixarene platform (Ruban...
Figure 1  (a) Asymmetric unit of compound 7 drawn with 30% probability ellipsoids. (b) Top and (c) side views of compound 7 in its crystal structure drawn as arbitrary radii sticks. In all panels, hydrogen atoms were omitted for clarity; the labeling scheme of calixarene phenyl rings is shown, and non-covalent intramolecular contacts are shown as dashed green sticks. The two conformations of each upper rim substituent pointing outwards from the cone are also exhibited in all panels [their site occupancy is given in (a)].

Besides stabilizing the conformation of imine-based calix[4]arenes, π⋯π interactions are also well-known in their recognition of guests, as occurs in benzimidazole-functionalized calix[4]arenes used as receptors for explosive molecules (Kandpal et al., 2013).

The two π⋯π stacked phenyl rings are not coplanar in relation to calixarene phenyl rings 1 and 3 to which they are attached, with angles between their least-square planes of 53.2(2)° and 50.8(3)° in 7 or 44.55(13)° and 46.43(11)° in 10. Such absence of coplanarity between the substituents and calixarene phenyl rings is also found in the two substituents pointing outwards from the aromatic cavity. However, they are a little less bent than those pointing inwards the cone in 10. The angles between the least-square planes of the calixarene phenyl rings 2 and 4 and their substituents were found to be 48.1(4)° (55% occupancy)/30.2(6)° (45% occupancy) and 50.1(4)° (60% occupancy)/39.6(7)° (40% occupancy) in 7 or 23.36(11)° and 27.23(13)° in 10.

As can be noted from the last planarity descriptions, both upper rim substituents attached to calixarene phenyl rings 2 and 4 of compound 7 are disordered over two sets of atomic sites with different occupancy factors. This phenomenon is due to the fact that both substituents can adopt two conformations changed by a rotation of approximately 180° on the N—C single bond axis between the substituent and the calixarene fragments (Fig. 1). Additionally, in this compound, all upper rim substituents are stabilized by the formation of S1(6) motifs wherein ortho-hydroxy groups act as intramolecular hydrogen bond donors to the imine nitrogen. The hydrogen bonding geometry of these motifs is shown in Table 1.

Butyl ether moieties bonded to calixarene phenyl rings 1 and 3 are present in similar syn conformations in which the carbon chain points outwards from the cone (see Figs. 1c and 2c). On the other hand, corresponding moieties attached to phenyl rings 2 and 4 adopt conformations resembling an anti-shaped chain with their bonded oxygen and carbon atoms pointing inwards and the remaining chain directed outwards from the cone.

It is noteworthy that single crystals of the main antifungal compound 11 (see in sequence) were obtained from dimethylformamide solution as large needles (ca. 1 mm in the largest dimension). However, they did not diffract X-rays above 1.5 Å resolution shell, even after using beam source from Cu anode under high exposure time of 60 s. Therefore, we concluded that these crystals did not have long-range order and consequently their crystal structure was not solved in the different X-ray diffraction dataset collected. However, its monoclinic unit cell was determined (a = 14.79(3) Å, b = 33.55(9) Å, c = 13.41(3) Å, β = 100.68(8)°, V = 6581(27) Å³, see unit cell data for compound 11 in the Experimental section). It was found to be similar to that of the monoclinic unit cell found for the related compounds 7 (a = 12.405(5) Å, b = 30.137(12) Å, c = 17.782(7) Å, β = 101.502(9)°, V = 6514(4) Å³) and 10 (a = 13.713(4) Å, b = 28.956(9) Å, c = 17.592(6) Å, β = 103.184(18)°, V = 6801(4) Å³). Therefore, the determined unit cell of 11 is compatible with four molecules thereof, which can be related by symmetry elements of the monoclinic space group P21/c, as occurs in 7 and 10. Thus, the unit cell data of 11 are in agreement with its expected molecular structure, in which it adopts a pinched cone conformation observed in its analogs. In order to evaluate and sug-

Figure 2  (a) Asymmetric unit of compound 10 drawn with 30% probability ellipsoids. (b) Top and (c) side views of compound 10 in its crystal structure drawn as arbitrary radius sticks. In all panels, hydrogen atoms were omitted for clarity; the labeling scheme of calixarene phenyl rings is shown, and the non-covalent intra-molecular contact is shown as dashed green sticks.
suggest the presence of the symmetry elements of the \( P2_1/c \) space group, we have checked carefully the systematic extinctions. There are only eight \( 0k0 \) reflections. Neither of them has violated the systematic extinction condition for the presence of the \( 2_1 \) screw axis symmetry element, i.e., no reflection with odd \( k \) was observed (mean \( \text{Int.}/\sigma(\text{Int.}) = 0.0 \)). This analysis suggests the presence of a \( 2_1 \) screw axis parallel to the \( b \) axis, but this is not conclusive due to the low number of \( 0k0 \) reflections. Likewise, 75 \( h0l \) reflections were observed, and neither of them has violated the systematic extinction condition for occurrence of a \( c \)-glide perpendicular to the \( b \) axis, i.e., no \( h0l \) reflection with odd \( l \) was detected (mean \( \text{Int.}/\sigma(\text{Int.}) = 0.0 \)). Therefore, the presence of \( c \)-glide symmetry element can be stated more surely in this structure. In this way, compound 11 can be arranged in the solid phase with the \( P2_1/c \) space group symmetry elements.

### 3.3. Antifungal activity

As shown in Table 2, wherein the MIC values obtained for each compound are presented, inhibition of all six tested Candida strains by iminecalix[4]arenes 6–11 was higher than their respective monomers. This indicates a general increase in antifungal potency of the aldimine monomers upon their cyclization into calixarene platform. Such a conclusion does open a newer perspective of enhancing the antifungal profile of well-known fungicidal compounds through their cyclization or even anchoring them on calixarene grounds. The ratio between the respective monomers. This indicates a general increase in antifungal property through the decoration of this phenyl ring occurred in compound 6 present with 2-hydroxyl group (MIC of 0.11 mmol L\(^{-1}\)) against C. parapsilosis). However, decoration of phenyl ring with 3,4-methylenedioxy does not change the antifungal property of the iminecalix[4]arene 10 (MIC of 0.41 mmol L\(^{-1}\)) against five Candida species. Among the monomers, this trend is not observed. Fluoro derivative 17 has presented the same high MIC of 3.77 mmol L\(^{-1}\) against all Candida species. Undecorated aldimine 14 had the highest MIC of 4.04 mmol L\(^{-1}\) against two species, but the compounds 15, 16 and 18 also showed higher MIC values of 3.80, 3.43 and 3.44 mmol L\(^{-1}\), respectively. The only similarity with iminecalix[4]arenes is the conservation of the lowest MIC values within the set of the monomers for the nitrofuran derivative 19, which has shown against C. krusei a MIC value of 0.22 mmol L\(^{-1}\) comparable to that of the calixarene-based compounds. This states that nitrofuran group attached to phenyl moiety increases the antifungal activity of the aldimine and its cyclic analog.

* Flu stands for fluconazole (positive control).
4. Conclusion

Six iminecalix[4]arenes and their corresponding monomeric units have been synthesized in this study with moderate to good yields. Their structural backbones were confirmed using IR, $^1$H NMR, $^{13}$C NMR and mass spectroscopy data. In addition, crystal structures of two iminecalix[4]arenes provided interesting conformation knowledge thereof. Both compounds have assumed pinched cone conformation kept stable by means of weak intramolecular $\pi-\pi$ interaction between phenyl rings from upper rim substituents pointing inwards the calixarene cavity. These substituents and those pointing outwards from the cone are twisted relative to calixarene phenyl rings in which they are bonded.

From the antifungal profile, it was possible to conclude that calixarene-based aldimines are more active against Candida strains than their monomers. Such an increase in the antifungal property of iminecalix[4]arenes has achieved up to 35.60 times higher activity than the corresponding monomeric molecule. Such a conclusion do es open a new perspective of enhancing the antifungal profile of well-known fungicidal compounds through their cyclization or even anchoring them in calixarene grounds. Lastly, the antifungal response of the iminecalix[4]arene with nitrofuran moiety was comparable to that of fluconazole. Our target compound was twice more active than necalix[4]arenes with nitrofuran moiety was comparable to that of fluconazole. From the antifungal profile, it was possible to conclude that calixarene-based aldimines are more active against Candida strains than their monomers. Such an increase in the antifungal property of iminecalix[4]arenes has achieved up to 35.60 times higher activity than the corresponding monomeric molecule. Such a conclusion does open a new perspective of enhancing the antifungal profile of well-known fungicidal compounds through their cyclization or even anchoring them in calixarene grounds. Lastly, the antifungal response of the iminecalix[4]arene with nitrofuran moiety was comparable to that of fluconazole. Our target compound was twice more active than necalix[4]arenes with nitrofuran moiety was comparable to that of fluconazole. This finding highlights the fact that such iminecalix[4]arenes can act as promising antifungal agents. Additionally, it can also guide the search for more powerful antifungal analogs supported on calixarene platform.
