Abstract: *Aspergillus* comprises a diverse group of species based on morphological, physiological and phylogenetic characters, which significantly impact biotechnology, food production, indoor environments and human health. *Aspergillus* was traditionally associated with nine teleomorph genera, but phylogenetic data suggest that together with genera such as *Polypaecilum*, *Phialosimplex*, *Dichotomomyces* and *Cristaspora*, *Aspergillus* forms a monophyletic clade closely related to *Penicillium*. Changes in the International Code of Nomenclature for algae, fungi and plants resulted in the move to one name per species, meaning that a decision had to be made whether to keep *Aspergillus* as one big genus or to split it into several smaller genera. The International Commission of *Penicillium* and *Aspergillus* decided to keep *Aspergillus* instead of using smaller genera. In this paper, we present the arguments for this decision. We introduce new combinations for accepted species presently lacking an *Aspergillus* name and provide an updated accepted species list for the genus, now containing 339 species. To add to the scientific value of the list, we include information about living ex-type culture collection numbers and GenBank accession numbers for available representative ITS, calmodulin, β -tubulin and *RPB2* sequences. In addition, we recommend a standard working technique for *Aspergillus* and propose calmodulin as a secondary identification marker.

Key words: Fungal identification, Phylogeny, Media, Nomenclature.

Taxonomic novelties: **New names:** *Aspergillus baarnensis* Samson, Visagie & Houbraken, *Aspergillus chinensis* Samson, Visagie & Houbraken, *Aspergillus delacroixii* Samson, Visagie & Houbraken, *Aspergillus jaipurensis* Samson, Visagie & Houbraken, *Aspergillus solicola* Samson, Visagie & Houbraken; **New combinations:** *Aspergillus arxii* (Fort & Guarro) Houbraken, Visagie & Samson, *Aspergillus assulatus* (S.B. Hong, Frisvad & Samson) Houbraken, Visagie & Samson, *Aspergillus astellatus* (Fennell & Raper) Houbraken, Visagie & Samson, *Aspergillus australensis* (Samson, S.B. Hong & Varga) Houbraken, Visagie & Samson, *Aspergillus caninus* (Sigler, Deanna A. Sutton, Gibas, Summerb. & Iwen) Houbraken, Tanney, Visagie & Samson, *Aspergillus capsici* (J.F.H. Beyma) Houbraken, Visagie & Samson, *Aspergillus cejpaii* (Milko) Samson, Varga, Visagie & Houbraken, *Aspergillus chlamydosporus* (Gené & Guarro) Houbraken, Tanney, Visagie & Samson, *Aspergillus denticulatus* (Samson, S.B. Hong & Frisvad) Samson, S.B. Hong, Visagie & Houbraken, *Aspergillus desertorum* (Samson & Mouch.) Samson, Visagie & Houbraken, *Aspergillus ferenczii* (Varga & Samson) Samson, Varga, Visagie & Houbraken, *Aspergillus galapagensis* (Frisvad, S.B. Hong & Samson) Samson, Frisvad & Houbraken, *Aspergillus inflatus* (Stolk & Malla) Samson, Frisvad, Varga, Visagie & Houbraken, *Aspergillus insolitus* (G. Sm.) Houbraken, Visagie & Samson, *Aspergillus papuensis* (Samson, S.B. Hong & Varga) Samson, S.B. Hong & Varga, *Aspergillus pisci* (A.D. Hocking & Pitt) Houbraken, Visagie & Samson, *Aspergillus pluriseminatus* (Stchigel & Guarro) Samson, Visagie & Houbraken, *Aspergillus sclerotialis* (W. Gams & Breton) Houbraken, Tanney, Visagie & Samson, *Aspergillus shendawei* (Yaguchi, Abliz & Y. Horie) Samson, Visagie & Houbraken, *Aspergillus similis* (Y. Horie, Udagawa, Abdullah & Al-Bader) Samson, Visagie & Houbraken, *Aspergillus tsunodae* (Yaguchi, Abliz & Y. Horie) Samson, Visagie & Houbraken.

INTRODUCTION

Aspergillus is a diverse genus with high economic and social impact. Species occur worldwide in various habitats and they are known to spoil food, produce mycotoxins and are frequently reported as human and animal pathogens. Furthermore, many species are used in biotechnology for the production of various metabolites such as antibiotics, organic acids, medicines or enzymes, or as agents in many food fermentations. The classification and identification of *Aspergillus* has been based on phenotypic characters but in the last decades was strongly influenced by molecular and chemotaxonomic characterisation.

Micheli (1729) introduced the name *Aspergillus*, with Haller (1768) validating the genus and Fries (1832) sanctioning the generic name. *Aspergillus glaucus* (L.) Link [= *Mucor glaucus* L. $\equiv$ *Monilia glauca* (L.) Pers.] is the generic type. In total, nine

teleomorph genera were traditionally linked to *Aspergillus* anamorphs (Pitt *et al.* 2000), one of these being *Eurotium* Link: Fr. typified by *Eurotium herbariorum* (Wiggers: Fr.) Link. The others were *Chaetosartorya* Subram., *Emericella* Berk., *Fennellia* B.J. Wiley & E.G. Simmons, *Hemicarpenteles* A.K. Sarbhoy & Elphick (now considered to belong in *Penicillium*; Visagie *et al.* 2014a), *Neosartorya* Malloch & Cain, *Petromyces* Malloch & Cain, *Sclerocleista* Subram. (now considered distinct from *Aspergillus*; Houbraken & Samson 2011) and *Stilbothamnium* Henn. *Neopetromyces* Frisvad & Samson and *Neocarpenteles* Udagawa & Uchiy. were introduced more recently by Frisvad & Samson (2000) and Udagawa & Uchiyama (2002). Thom & Raper (1945) and Raper & Fennell (1965) published major monographic treatments on the genus *Aspergillus* and respectively accepted 89 and 150 species. They also disregarded teleomorphic names, contrary to the prevailing nomenclatural code,

using only the name *Aspergillus*. The List of “Names in Current Use” (NCU) for the family *Trichocomaceae* (Pitt & Samson 1993) accepted 185 anamorphic *Aspergillus* names and 72 associated teleomorphic names. Pitt *et al.* (2000) updated this list, accepting 184 *Aspergillus* and 70 associated teleomorphic names. Both lists were mainly based on the morphological species concept current at that time. However, the move towards a polyphasic species concept incorporating morphology, extrolite data and most importantly phylogenetic data, meant that this list quickly became out-dated. This is not only because new species were described since the late 1990's, but was also a reflection that many species previously considered synonyms based on morphology were shown to be phylogenetically distinct. Old names were thus often re-introduced as accepted, distinct species. As such, we consider updating the list of accepted species to be crucial for the taxonomic and nomenclatural stability of *Aspergillus*.

The infrageneric classification of the genus *Aspergillus* is traditionally based on morphological characters. Raper & Fennell (1965) divided the genus in 18 groups. The classification into groups does not have any nomenclatural status and therefore Gams *et al.* (1985) introduced names of subgenera and sections in *Aspergillus*. The phenotype based classification of subgenera and sections largely correspond with the current published phylogenies. Peterson (2008) accepted five subgenera and 16 sections in *Aspergillus*. Houbraken *et al.* (2014) and Hubka *et al.* (2014) currently proposed four subgenera (*Aspergillus*, *Circumdati*, *Fumigati* and *Nidulantes*) and 20 sections. Phylogenetic studies (Berbee *et al.* 1995, Ogawa *et al.* 1997, Tamura *et al.* 2000, Geiser *et al.* 2008, Peterson 2008, Peterson *et al.* 2008, Houbraken & Samson 2011) shed light on the relationships between *Aspergillus* species, but left questions regarding the generic concept unsolved. Because of the new single name nomenclature for fungi (McNeill *et al.* 2012), it is important to define the phylogenetic relationships of species in *Aspergillus* and closely related genera. Morphological identification of *Aspergillus* mostly follows the protocols of Raper & Fennell (1965), Klich (2002), Pitt & Hocking (2009) and Samson *et al.* (2010). Molecular tools, especially phylogenetic species recognition, are increasingly being used with the internal transcribed spacers of the nrDNA (ITS) now accepted as the official DNA barcode for fungi (Schoch *et al.* 2012). However, this locus is insufficient for correctly identifying all *Aspergillus* species and thus a secondary identification marker is needed. In this paper, we discuss different approaches for species identification in *Aspergillus*. We make recommendations for identifying and characterising *Aspergillus* species and recommend DNA markers for reliable species identification.

MONOPHYLY OF ASPERGILLUS

Aspergillus has been the subject of a large number of taxonomic studies using DNA sequence data. Many of these studies focused on specific groups (species, sections, subgenera) within *Aspergillus* and the number of phylogenetic studies at the genus level and above are limited. The first studies on the phylogeny of *Aspergillus* and related genera often used a limited number of strains and phylogenetic markers. Using a dataset of 17 strains, Berbee *et al.* (1995) studied the possible monophyly of *Penicillium* using ITS and 18S rDNA sequences. In this study, *Eupeenicillium javanicum* (= *Penicillium javanicum*), *Monascus*

purpureus, *Neosartorya fischeri* (= *A. fischeri*), *Eurotium rubrum* (= *A. ruber*) and *A. fumigatus* form a well-supported clade (98 % bootstrap value, bs) indicating the close relationship among these species. Furthermore, *A. ruber*, *A. fumigatus* and *A. fischeri* were placed together on a branch with moderate statistical support (77 % bs), indicating that *Aspergillus* is monophyletic. Similar results were found by Ogawa *et al.* (1997); in their phylogeny based on 18S rDNA data, *E. rubrum*, *N. fischeri* and *A. fumigatus* also formed a well-supported clade (99 % bs), distinct from *Penicillium* and *Monascus*. Tamura *et al.* (2000) determined the relationships within *Aspergillus* using 18S rDNA. Using a larger sample size, data indicate that *Aspergillus* is monophyletic, but the overall resolution was limited.

Peterson (2008) studied the phylogenetic relationships within *Aspergillus*. A phylogeny based on 5.8S rDNA, 28S rDNA and the *RPB2* sequences resolved *Aspergillus* into three main clades, but the relationship among these clades was not statistically supported. These clades roughly corresponded with the subgenera of *Aspergillus*, with one clade including the subgenera *Circumdati* and *Fumigati*, one representing subgenus *Nidulantes* and another containing members of subgenus *Aspergillus*. Similar results were obtained by Geiser *et al.* (2008), although they focused on *Aspergillus* below genus level. Using a 10-gene phylogeny, *Aspergillus* could be split in three main clades: subgenera *Circumdati*, *Fumigati* and *Nidulantes*. No strains belonging to subgenus *Aspergillus* were included in this study. The study of Peterson (2008) further showed that a clade comprising *Monascus* and *Hamigera* species was basal to *Aspergillus* (0.98 posterior probability, pp) and formed a polytomy with clades containing *Penicillium* and *Sclerocleista* species (1.00 pp).

The studies by Houbraken & Samson (2011) and Houbraken *et al.* (2014) used a four-gene phylogeny (*RPB1*, *RPB2*, *Tsr1* and *Cct8*) and were based on similar data sets. Using Maximum Likelihood analysis, both studies resolved *Aspergillus* and its teleomorphs in a monophyletic clade without statistical support (51 and 57 %). A Bayesian analysis was also performed in the study of Houbraken & Samson (2011) and in this analysis, *Aspergillus* and its sexual states formed a fully supported lineage (1.00 pp). This data is in agreement with that of Houbraken *et al.* (2014), where a 25-gene phylogeny shows the monophyly of *Aspergillus* and its teleomorphs (100 % bs). In common with the Peterson (2008) and Geiser *et al.* (2008) studies, the genus could be subdivided into several clades. Three of those clades (subgenera *Aspergillus*, *Nidulantes*, *Fumigati*) were fully supported in the Bayesian analysis (1.00 pp) and the clade representing subgenus *Circumdati* was moderately supported (0.94 pp). Interestingly, the type species of *Dichotomomyces*, *Polypaecilum* and *Phialosimplex* were related to members of sections *Cremeri* and *Aspergillus* (64 % bs, 1.00 pp), placing those genera within *Aspergillus*. This was unexpected, because species of the genera *Polypaecilum* and *Phialosimplex* do not produce typical *Aspergillus* conidiophores. *Phialosimplex* was introduced rather recently by Sigler *et al.* (2010). Species of this genus are closely related in their phylogenies (84 % MP, 18S rDNA; 89 % MP; ITS), and were phylogenetically set apart from *Aspergillus* and *Penicillium*, but with low or insignificant support. Based on the data of Houbraken & Samson (2011), combined with phenotypic and physiological characters, *Aspergillus* could be divided into six subgenera: *Circumdati*, *Nidulantes*, *Aspergillus*, *Fumigati*, *Polypaecili* and *Cremeri*. This was also supported in the study of Houbraken *et al.* (2014), where based on a 25-

gene phylogeny, *Aspergillus* and *Penicillium* resolved in two separate fully supported clades. Furthermore, *Aspergillus* could be divided into five clades (no representatives of *Phialosimplex* or *Polypaecilum* were included in this study).

Subgenera listed above are strongly linked with teleomorph genera. The teleomorph genus *Eurotium* is linked to subgenus *Aspergillus* and the genera *Petromyces*, *Neopetromyces* and *Fennellia* belong to subgenus *Circumdati*. *Neocarpenteles*, *Neosartorya* and *Dichotomomyces* belong to subgenus *Fumigati*; *Chaetosartorya* and *Cristaspora* to subgenus *Cremeri* and *Emericella* to subgenus *Nidulantes*. These subgenera also have distinct physiological and phenotypic characters and this data could advocate splitting the genus in six different genera.

Using a subset of sequences generated by Houbroken & Samson (2011), Pitt & Taylor (2014) re-analysed the phylogenetic relationships of *Aspergillus* and closely related genera. In their analysis, only members of the *Aspergillaceae* were included and Bayesian and ML analyses were performed. In the Bayesian analysis, the deeper nodes were generally well-supported; in contrast, the support for these nodes in the ML analysis was poor. Below the genus level, Pitt & Taylor (2014) found that *Penicillium* is a sister clade of *Nidulantes*, rendering *Aspergillus* a paraphyletic genus. Based on this and other data (phenotype, physiology) they advocated splitting *Aspergillus* into several genera in part to maintain the monophyly of, and the use of the name *Penicillium*. Pitt & Taylor (2014) speculated that the difference between their analysis and that of Houbroken & Samson (2011) was an improved alignment obtained by omitting more distantly related taxa. This seems unlikely, because the genes sampled consisted of exon sequence only, which results in alignments with almost no gaps. The reason for the inconsistencies among these studies remains unknown.

The deep, basal branches are often short and weakly supported in most studies dealing with the phylogeny of *Aspergillus* and related genera (Houbroken & Samson 2011, Houbroken et al. 2014, Pitt & Taylor 2014). Room exists for argument about the exact relationships among *Penicillium*, *Aspergillus* and related genera. Although based on a limited number of species, the phylogeny of Houbroken et al. (2014) confidently shows the monophyly of *Aspergillus*. An increase of sample size and the analysis of more loci will lead to increased statistical support of the deeper nodes. Based on the recent 25-gene phylogeny, *Penicillium* and *Aspergillus* are divided in two distinct well-supported genera, suggesting the monophyly of both genera (Houbroken et al. 2014). In the near future, genome sequence data will become available and analysis of this data will probably result in well-supported phylogenies.

THE *ASPERGILLUS* CONIDIOPHORE

As mentioned above, Houbroken & Samson (2011) demonstrated that the type species of *Polypaecilum* and *Phialosimplex* were related to members of sections *Cremeri* and *Aspergillus*, phylogenetically placing those genera within the classical concept of *Aspergillus*. This was unexpected, because species of *Polypaecilum* and *Phialosimplex* do not produce a typical *Aspergillus* conidiophore. Pitt & Hocking (1985) suggested that, “simultaneously produced phialides and a foot cell are absolute characters for assigning a species to the *Aspergillus* genus”. However, based on phylogenetic analyses, the production of an aspergillum-like conidial head does not guarantee that a given

species belongs to *Aspergillus*. For example, “*Aspergillus paradoxus*”, “*A. malodoratus*” and “*A. crystallinus*” produce conidial heads with a terminal vesicle reminiscent of *Aspergillus*, yet belong to *Penicillium* subgenus *Penicillium* (Houbroken & Samson 2011, Visagie et al. 2014a, 2014b). On the other hand, species lacking typical *Aspergillus*-like asexual structures are nested within the *Aspergillus* clade (Houbroken & Samson 2011). An example is *Penicillium inflatum* (Stolk & Malla 1971), which produces *Penicillium*-like conidial heads, although it belongs to *Aspergillus* section *Cremeri*. Recent multilocus phylogenetic studies also clarified that genera with conidial heads that are dramatically different from a typical aspergillum, such as *Dichotomomyces* (Saito 1949, Scott 1970), *Phialosimplex* (Sigler et al. 2010), *Polypaecilum* (Smith 1961) and *Cristaspora* (Fort & Guarro 1984) are nested within the broadly defined, monophyletic *Aspergillus* clade (Varga et al. 2007a, Peterson 2008, Houbroken & Samson 2011). Moreover, there are some *Aspergillus* species that do not produce asexual structures, which makes it difficult to assign them to a genus usually recognised by asexual morphological characters. An example is *A. monodii* (syn. *Fennellia monodii*; Locquin-Linard 1990), which is assigned to *Aspergillus* section *Usti* based on a polyphasic taxonomic approach (Samson et al. 2011). Repeated attempts were made to induce conidiogenesis in this species, without success. Additionally, several genera have conidial heads resembling vesiculate *Aspergillus* conidiophores and/or with branching similar to *Penicillium*, including *Paecilomyces* (Samson et al. 2010), *Goidanichiella* (Kwasna & Behnke-Borowczyk 2010), or *Nalanthamala* (Schroers et al. 2005). These genera are unrelated or only distantly related to *Aspergillaceae*.

Previous studies on the genetics and molecular biology of conidiogenesis in *A. nidulans* and other aspergilli provide another proof that the production of an aspergillum is neither sufficient nor a prerequisite to assign a species to *Aspergillus*, because mutations in the developmental pathway lead to the formation of conidium-bearing structures not resembling an aspergillum. *Aspergillus nidulans* is a model fungus for the examination of the genetics and molecular biology of conidiophore development (Clutterbuck 1969, Miller 1993, Adams et al. 1998). Several genes take part in this process (for details, see Adams et al. 1998, Harris 2012) and conidiogenesis is under complex genetic control. In *A. nidulans*, *FluG* (associated with the production of a small diffusible molecule) and *FlbA* (regulator of G-protein signalling) are upstream activators of conidiation (Adams et al. 1998). Several additional downstream transcription factors (*FlbB*, *FlbC*, *FlbD*, *FlbE*) are required for transcriptional activation of the key component of the pathway, the transcription factor *BrlA*. This factor activates the transcription factors *AbaA* and *WetA* in the pathway that includes multiple feedback loops and is regulated by additional modifiers (e.g. *MedA* and *StuA*; Adams et al. 1998, Harris 2012). Most components of the pathway are conserved in other *Aspergillus* and *Penicillium* species, suggesting that this regulatory network has been conserved within the *Aspergillaceae* (Borneman et al. 2000, Yu et al. 2006, Ogawa et al. 2010, Yu 2010, Sigl et al. 2011). Mutations in these genes can lead to dramatic changes in the morphology of the conidial head (Harris 2012). A mutation in a tyrosine kinase gene (*AnkA*) or the cyclin-dependent cyclase *nimX* leads to the appearance of septa in the stalk, absence of a terminal vesicle, and the failure to produce proper metulae and phialides because of a failure to undergo the transition from “hyphal-like” to “yeast-like” growth (Ye et al. 1997, 1999, Harris 2012). Mutations in the *RgaA* locus

(homologue of the yeast GTPase-activating protein *Rga1*) lead to abnormal conidiophores that do not possess a terminal vesicle and form metulae that resemble hyphae (Harris 2012). Other mutations can also lead to the transition of *Aspergillus*-like conidial heads to *Penicillium*-like heads, including deletion mutants of *nimX* (Harris 2012) or a Pcl-like cyclin (Schier et al. 2001), and other mutants described in the literature like the Abnc and V103 mutants of *A. nidulans* (Giancoli & Pizzinari-Kleiner 2004, Giancoli et al. 2010).

Apart from the typical aspergillum, several *Aspergillus* species produce other types of conidium-bearing structures. Several *A. versicolor* and *A. sydowii* isolates consistently produce diminutive conidial heads, which resemble penicillate (*Penicillium*-like) conidiophores (Raper & Fennell 1965). *Aspergillus implicatus* (section *Usti*, Samson et al. 2011), *A. unilateralis* (section *Fumigati*, Samson et al. 2007), *A. candidus* and other species in section *Candidi* (Varga et al. 2007b) produce diminutive conidial heads that are frequently uniseriate, in contrast with the larger biseriate heads, and sometimes reminiscent of *Penicillium* heads, while *A. terreus* (Deak et al. 2009, 2011), *A. flavipes*, *A. niveus* (Pore & Larsh 1968) and *A. alabamensis* (Burrough et al. 2012) isolates frequently produce accessory conidia in addition to the typical conidial heads.

We suggest that the conidium-bearing apparatus of species of *Dichotomomyces*, *Phialosimplex* and the type species of *Polypaecilum* (Fig. 1), which form part of the monophyletic *Aspergillus* clade, evolved from *Aspergillus*-like conidial heads by mutations in the regulatory genes. Harris (2012) proposed that the *Aspergillus*-like conidial head might have evolved from a penicillus producing ancestor. Moreover, the observations that mutations in several genes taking part in the control of conidiogenesis can lead to the transition of an aspergillum to structures resembling a penicillus, indicate that the aspergillum is more ancient than a penicillus. Full genome sequencing of these isolates would enable studies aimed at determining the molecular basis for these differences, and would help to understand the evolution of conidiophore development in the *Aspergillaceae*.

In conclusion, the production of *Aspergillus*- or *Penicillium*-like conidial heads is essential for assigning a species to a given genus. The polythetic morphological definition of both *Aspergillus* and *Penicillium* adopted in this paper acknowledges that while certain conidiophore patterns are typical of 90 % or more of the included species, other patterns may occur in a minority of species. Recent data indicate that a polyphasic approach should be used for species assignment including sequence-based identification (Samson et al. 2007).

NOMENCLATURE OF ASPERGILLUS AND ITS SEXUAL MORPHS

Recently, a proposal to dramatically revise article 59 of the former botanical code was accepted by the 2011 International Botanical Congress Nomenclature Section at Melbourne and the principle of "one fungus : one name" was established (Norvell 2011, McNeill et al. 2012). These new nomenclatural rules have large implications for *Aspergillus* and several options were considered by a meeting of the International Commission of *Penicillium* and *Aspergillus* (ICPA) in April 2012. In this paper, we review the arguments leading to our decision to maintain the prevailing, broad concept of *Aspergillus*, with the modifications included in the diagnosis below.

One option is to split *Aspergillus* into several clades and use the oldest genus name associated with the resulting genera, such as *Neosartorya*, *Emericella*, *Petromyces*, etc. The type species of *Aspergillus* is *A. glaucus* (section *Aspergillus*). This would mean that the name *Eurotium* would be lost and the genus name *Aspergillus* would be applied only to this clade. Species in other clades, such as in section *Fumigati* would be renamed as *Neosartorya*, subgenus *Nidulantes* as *Emericella* and subgenus *Circumdati* as *Petromyces*, although there may be older anamorph generic names for each clade (cf. Seifert et al. 2011). Pitt & Taylor (2014) argued for using *Aspergillus*, in place of *Petromyces* for subgenus *Circumdati* because no more than five of the many currently accepted species possess a known sexual state in *Petromyces*, while several of these commonly occurring species, such as *A. niger*, *A. ochraceus* and *A. flavus*, are economically important. These arguments are debatable because the same argument could be used for section *Fumigati* where the medical community could have problems accepting the *Neosartorya* name.

Option two follows from the first option to split *Aspergillus* into several genera with different (teleomorph) names, and conserve *Aspergillus* with another type species (e.g. *A. fumigatus* or *A. niger*). If *A. niger* were chosen, the genus name *Aspergillus* could be used for e.g. *A. niger*, *A. flavus*, *A. oryzae*, while *Emericella*, *Neosartorya* and *Eurotium* would then be used for species in sections *Versicolores*, *Fumigati* and *Aspergillus* (*Emericella* for *E. nidulans* and *A. versicolor*, *Neosartorya* for *A. fumigatus* and *A. clavatus*, and *Eurotium* for *E. herbariorum* and *A. penicillioides*). The selection of a type other than *A. glaucus* would provoke debate, because the choice would depend on the economic phenomenon of interest, e.g. *A. fumigatus* for medical mycology, *A. flavus* for food and mycotoxin related research or *A. nidulans* because of its use as a genetic model. The proposal to select a type other than *A. glaucus* would have to be prepared for the Nomenclatural Committee for the 2017 International Botanical Congress without the support of the International Commission of *Penicillium* and *Aspergillus* (ICPA). It would cause further instability and nomenclatural confusion.

Option three is to keep the name *Aspergillus* and treat other (teleomorph) names to indicate structures with biological significance, but always together with the *Aspergillus* name. e.g. *Aspergillus glaucus* with eurotium-type ascomata, or *Aspergillus fischeri* (neosartorya-type fruiting bodies). This option was chosen by ICPA on April 11, 2012 (<http://www.aspergilluspenicillium.org/images/PDF/minutes.pdf>). The consequence of this choice is that the majority of *Aspergillus* names, including their teleomorphs will keep their *Aspergillus* name, contributing to nomenclatural stability. The option to treat *Aspergillus* as one genus is strongly supported by the results of phylogenetic analyses that the genus is monophyletic with minor modifications to the classical concept needed. As discussed above, the small genera *Dichotomomyces*, *Polypaecilum* and *Phialosimplex* should be considered synonyms of *Aspergillus*.

The consequence of the single-name system is that teleomorph-based genera, such as *Neosartorya*, *Emericella*, *Eurotium*, and *Petromyces*, are synonymised with *Aspergillus*. This nomenclature is already being adopted in the recently published *Aspergillus* taxonomies. Hubka et al. (2013a) used a single-name nomenclature in their revision of the genus *Eurotium* and all accepted *Eurotium* taxa were listed under their *Aspergillus* names. Examples of species producing sexual states, but described as *Aspergillus* include *A. waksmanii* (Hubka et al.

Fig. 1. Range of conidiophore phenotypes, which phylogenetically belong in *Aspergillus*. A, B. *Basipetospora halophila* (CBS 232.32). C, D. *Dichotomomyces cejpji* (CBS 157.66). 2013b), *A. felis* (Barrs et al. 2013), *A. huiyanae* (Matsuzawa et al. 2014a), *A. siamensis* (Eamvijarn et al. 2013), *A. caatingaensis* and *A. pernambucoensis* (Matsuzawa et al. 2014b), and *A. wyomingensis* (Nováková et al. 2014) for species with a neosartorya-type sexual morph, while *A. cibarius* (Hong et al. 2012), *A. osmophilus* (Asgari et al. 2014) and *A. cumulatus* (Kim et al. 2014) were introduced for species with a eurotium-type sexual state.

RECOMMENDED METHODS FOR THE IDENTIFICATION AND CHARACTERISATION OF *ASPERGILLUS*

Morphological species recognition

Morphological characters

Morphology forms an important part of the species concept of *Aspergillus*. Colony characters used for characterising species include colony growth rates, texture, degree of sporulation, production of sclerotia or cleistothecia, colours of mycelia, sporulation, soluble pigments, exudates, colony reverses, sclerotia, Hülle-cells and cleistothecia. Both sexual and asexual reproduction occurs in *Aspergillus* and the microscopic features of these structures are important. Diagnostic conidiophore characters include the shape of conidial heads, the presence or absence of metulae between vesicle and phialides (i.e. uniseriate or biseriate), colour of stipes, and the dimension, shape and texture of stipes, vesicles, metulae (when present), phialides, conidia and Hülle-cells (when present). The same applies for cleistothecia, asci and ascospores. For cleistothecia, the development of ascomata and the way their walls are produced is also an important character. Ascospore sizes and morphology, particularly the often diagnostic ornamentation (roughening, rims, wings, furrows, etc.) are important for identifying species. Media, inoculation technique and incubation conditions affect morphological characters (Okuda 1994, Okuda et al. 2000). We recommend the following standardised method for laboratories working with *Aspergillus* (summarised in Fig. 2).

Inoculations

Inoculations are made from spore suspensions prepared in a 30 % glycerol SS-buffer (0.5 g/l agar, 0.5 g/l Tween 80) solution, which can be stored at -80°C . Alternatively, spore suspensions can be made in a 0.2 % agar and 0.05 % Tween 80 solution, and stored at 4°C . Plates are inoculated in three-point pattern using a micropipette and inoculum size of 0.5–1 μl per spot.

Medium preparation

For media preparation, we recommend using 90 mm Petri dishes with 20 ml medium per plate (Okuda 1994, Okuda et al. 2000). Glass Petri dishes were used traditionally, but vented or unvented polystyrene dishes have mostly replaced these. Vented Petri dishes allows for more oxygen transfer and thus more typical conidiophore morphology than unvented dishes. However, not all institutions use vented dishes. Media recommended as standard for *Aspergillus* include Czapek Yeast Autolysate agar (CYA) and Malt Extract agar (MEA, Oxoid). Although we propose the use of Oxoid MEA, many laboratories use Difco. It is thus important to mention in descriptions which

brand of malt extract is used. In addition, two different MEA formulations are used in recent descriptions. Blakeslee's (1915) MEA is traditionally used because it was a standard used by Raper & Fennell (1965), but CBS uses a differently formulated MEA (summarised in Table 1) from which a large number of species has been described recently. It is thus important to also note this formulation in species descriptions. To observe a wider range of characters it is useful to use additional media, including Czapek's agar (CZ), 20 % sucrose CYA (CY20S), 20 % sucrose MEA (MEA20S), Yeast Extract Sucrose agar (YES), Dichloran 18 % Glycerol agar (DG18), Oatmeal agar (OA) and Creatine Sucrose agar (CREA). CZ was used by Raper & Fennell (1965) in their taxonomic treatment and is still widely used today. However, lately CYA has been more widely used. Media such as CY20S, ME20S and DG18 allow for growth of xerophilic *Aspergilli*, mostly classified in section *Aspergillus*, and are useful for the full development of diagnostic characters of these species. YES, together with CYA, is required for extrolite profiling of strains discussed below. Sexual reproductive structures are more readily produced on OA and thus can add valuable taxonomic information, even though we are aware that OA is very difficult to standardise across different laboratories. We do suggest, however, that pre-fabricated OA formulations or precooked oats ("3 minute oats") are unsuitable, and for best results organic uncooked oats should be used. Acid production is often a useful character and this is observed on the purple medium CREA, which turns yellow when acid is produced by colonies. For consistent conidial colours, the addition of zinc-sulphate and copper-sulphate as trace elements (1 g $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ and 0.5 g $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ in 100 ml distilled water) is of utmost importance because these metals vary widely in water sources in different locations and are critical for pigment production. Analytical grade inorganic chemicals are recommended for medium preparations. For optimal colony growth and colour, the type of agar plays also an important role and in some cases strongly influences these phenotypic characters. It is therefore important to test the agar for consistent character development. After extensive comparisons, So-BI-Gel agar (Bie & Berntsen, BBB 100030) is used at CBS. Medium formulations are summarised in Table 1.

Incubation

Inoculated CYA and MEA plates are incubated reverse side up at 25°C , with additional CYA plates incubated at 30 and 37°C . In section *Circumdati*, characters on CYA at 33°C have been shown to be taxonomically informative (Yilmaz et al. 2014, Visagie et al. 2014b), while growth on CYA at 45 – 50°C is informative for section *Fumigati*. Plates should be kept in the dark and to allow for sufficient aeration they should not be wrapped with Parafilm (Okuda et al. 2000). For standard bench top incubators, plates should not be placed in plastic boxes. Many laboratories use walk-in incubators where plates must be incubated in plastic boxes. In these cases, care should be taken to allow for sufficient aeration by, for example, not having too many plates in one box. Incubation times are standardised at seven days, after which colony growth rates and other characters should be recorded. Additional important characters are often observed by incubating cultures for longer periods of time, in particular characters of sclerotia or ascomata. In these cases it should be noted in descriptions.

Fig. 2. Flow diagram summarising recommended methods for the identification and characterisation of *Aspergillus*. Frisvad & Thrane (1987, 1993), Smedsgaard (1997) and Klitgaard *et al.* (2014), refer to methods described for detecting extrolites in fungi.

Table 1. Media used for morphological characterisation.**Czapek stock solution (100 ml) (Pitt 1979)**

NaNO ₃	30 g
KCl	5 g
MgSO ₄ ·7H ₂ O	5 g
FeSO ₄ ·7H ₂ O	0.1 g
dH ₂ O	100 ml

*Store at 4–10 °C

Trace elements stock solution (100 ml)

CuSO ₄ ·5H ₂ O	0.5 g
ZnSO ₄ ·7H ₂ O	0.1 g
dH ₂ O	100 ml

*Store at 4–10 °C

Blakeslee's Malt extract agar (MEAbI, Blakeslee 1915)

Malt extract (Oxoid)	20 g
Peptone (Oxoid)	1 g
Glucose	20 g
CuSO ₄ ·5H ₂ O	0.005 g
ZnSO ₄ ·7H ₂ O	0.01 g
Agar	20 g
dH ₂ O	1000 ml

*Mix well and autoclave at 121 °C for 15 min. pH 5.3 ± 0.2.

Creatine sucrose agar (CREA, Frisvad 1981)

Sucrose	30 g
Creatine·1H ₂ O	3 g
K ₃ PO ₄ ·7H ₂ O	1.6 g
MgSO ₄ ·7H ₂ O	0.5 g
KCl	0.5 g
FeSO ₄ ·7H ₂ O	0.01 g
CuSO ₄ ·5H ₂ O	0.005 g
ZnSO ₄ ·7H ₂ O	0.01 g
Bromocresol purple	0.05 g
Agar	20 g
dH ₂ O	1000 ml

*Mix well and autoclave at 121 °C for 15 min. pH 8.0 ± 0.2.

Czapek's agar (CZ, Raper & Thom 1949)

Czapek concentrate	10 ml
Sucrose	30 g
CuSO ₄ ·5H ₂ O	0.005 g
ZnSO ₄ ·7H ₂ O	0.001 g
Agar	20 g
dH ₂ O	1000 ml

*Mix well and autoclave at 121 °C for 15 min.

Czapek Yeast Autolysate agar (CYA, Pitt 1979)

Czapek concentrate	10 ml
Sucrose	30 g
Yeast extract (Difco)	5 g
K ₂ HPO ₄	1 g
CuSO ₄ ·5H ₂ O	0.005 g
ZnSO ₄ ·7H ₂ O	0.01 g
Agar	20 g
dH ₂ O	1000 ml

*Mix well and autoclave at 121 °C for 15 min. pH 6.2 ± 0.2.

Table 1. (Continued).**CYA with 20% sucrose agar (CY20S, Klich 2002)**

Czapek concentrate	10 ml
Sucrose	200 g
Yeast extract (Difco)	5 g
K ₂ HPO ₄	1 g
CuSO ₄ ·5H ₂ O	0.005 g
ZnSO ₄ ·7H ₂ O	0.01 g
Agar	20 g
dH ₂ O	1000 ml

*Mix well and autoclave at 121 °C for 15 min. pH 5.4 ± 0.2.

Dichloran 18% Glycerol agar (DG18, Hocking & Pitt 1980)

Dichloran-Glycerol-agar-base (Oxoid)	31.5 g
Glycerol (anhydrous)	220 g
CuSO ₄ ·5H ₂ O	0.005 g
ZnSO ₄ ·7H ₂ O	0.01 g
Chloramphenicol	0.05 g
Agar	20 g
dH ₂ O	1000 ml

*Mix well and autoclave at 121 °C for 15 min. After autoclaving, add 0.05 chlortetracycline. pH 5.6 ± 0.2.

Malt Extract agar (MEA, Samson et al. 2010)

Malt extract (Oxoid CM0059)	50 g
CuSO ₄ ·5H ₂ O	0.005 g
ZnSO ₄ ·7H ₂ O	0.01 g
dH ₂ O	1000 ml

*Mix well and autoclave at 115 °C for 10 min. pH 5.4 ± 0.2.

Malt Extract 20% Sucrose agar (M20S, Samson et al. 2010)

Malt extract (Oxoid CM0059)	50 g
Sucrose	200 g
CuSO ₄ ·5H ₂ O	0.005 g
ZnSO ₄ ·7H ₂ O	0.01 g
dH ₂ O	1000 ml

*Mix well and autoclave at 121 °C for 15 min. pH 5.4 ± 0.2.

Oatmeal agar (OA, Samson et al. 2010)

Oatmeal flakes	30 g
CuSO ₄ ·5H ₂ O	0.005 g
ZnSO ₄ ·7H ₂ O	0.01 g
Agar	20 g
dH ₂ O	1000 ml

*First autoclave flakes (121 °C for 15 min) in 1000 ml dH₂O. Squeeze mixture through cheese cloth and use flow through, topping up to 1000 ml with dH₂O with 20 g agar. Autoclave at 121 °C for 15 min. pH 6.5 ± 0.2.**Yeast extract sucrose agar (YES, Frisvad 1981)**

Yeast extract (Difco)	20 g
Sucrose	150 g
MgSO ₄ ·7H ₂ O	0.5 g
CuSO ₄ ·5H ₂ O	0.005 g
ZnSO ₄ ·7H ₂ O	0.001 g
Agar	20 g
dH ₂ O	885 ml

*Mix well and autoclave at 121 °C for 15 min. pH 6.5 ± 0.2.

Microscopy

As a standard, microscopic observations are made from conidiophores produced on MEA after 7–10 d, although other media can also be used when stated in descriptions. OA is good for observing cleistothecia in sexually competent species. Lactic acid (70 %) or Shear's solution works well as a mounting fluid (Samson *et al.* 2010). Lactophenol is corrosive and the phenol toxic, and as a result is not recommended as a mountant for slides. *Aspergillus* conidia are hydrophobic. As such, mounts can be washed with drops of 70 % ethanol to wash away excess conidia and prevent air-bubbles from being trapped. Fine needles can be used to tease apart tufts of conidiophores. For best observation of conidiophore characters, differential interference contrast microscopy (= Nomarski) is suggested when possible; we note that *Aspergillus* conidiophores are often birefringent, exhibiting colours that are artefacts of polarised light under DIC illumination and not indicative of pigmentation.

Molecular species recognition

Identification markers

The nuc rDNA internal transcribed spacer rDNA region (ITS1-5.8S-ITS2) is the official DNA barcode for fungi (Schoch *et al.* 2012), because it is the most frequently sequenced marker in fungi and has primers that work universally. As such, it is good practise to include ITS sequences whenever new species are described, although it sometimes does not contain enough variation for distinguishing among all species (Schoch *et al.* 2012). An ITS phylogeny of *Aspergillus* is provided as supplementary material (Fig. S1) to demonstrate the lack of variation in some clades. As such, a secondary barcode or identification marker usually is needed to identify an *Aspergillus* culture to species with confidence.

The secondary marker, similarly to ITS, should make use of universal primers, be easy to amplify and in contrast to ITS, should distinguish among all species. Another important consideration is the completeness of the current database available for each gene, i.e. how many species have in fact been

sequenced. Based on these criteria, there are three realistic options, namely calmodulin (*CaM*), β -tubulin (*BenA*) or the RNA polymerase II second largest subunit (*RPB2*). *RPB2* is not easy to amplify, rendering its use as secondary identification marker frustrating. In contrast, *BenA* is easy to amplify, but has been reported to vary in the number of introns and PCR sometimes results in the amplification of paralogous genes (Peterson 2008, Hubka & Kolarik 2012). A similar problem was noted in a strain of *A. udagawae* (CCF 4477), where available *CaM* primers amplified a pseudogene and the resulting phylogeny had a very long branch for this strain in the *A. udagawae* clade (Nováková *et al.* 2013). Otherwise, *CaM* is easy to amplify, distinguishes among all *Aspergilli* (except for *A. elegans* and *A. steynii*, where ITS distinguishes between them, Visagie *et al.* 2014b), as demonstrated in the gene tree included as supplementary material (Fig. S2). In addition, the *CaM* sequence database is almost complete for all accepted species. As such, from a practical point of view, we suggest the use of *CaM* as a temporary secondary identification marker in *Aspergillus*. A case study for *CaM* in the section *Nigri* is provided below. Primers and thermal cycle protocols commonly used for PCR amplification are summarised in Table 2.

A common problem experienced with sequence-based identifications is comparing newly obtained sequences with verified sequence databases. GenBank is a public, archival database, meaning that it accepts all sequences submitted and cannot always verify the taxonomic names attributed to the sequences. This results in BLAST searches that often give hits to misidentified sequences in the database. In a step towards cleaning up misidentified GenBank sequences, the RefSeq initiative was launched (<http://www.ncbi.nlm.nih.gov/refseq/>), which contains only verified ITS sequences (Schoch *et al.* 2014). For *Aspergillus*, all ex-type sequences were included in the RefSeq database. This should result in a great improvement of species identification based on ITS. However, for alternative genes there is no such database. In an attempt to aid identifications, GenBank accession numbers for *CaM* sequences of ex-type species are added to the accepted species list presented below. We have also included representative *BenA* and *RPB2*

Table 2. Primers and annealing temperatures used for amplification and sequencing.

sequences when they are available. These can be downloaded from GenBank and used for creating a local BLAST file to aid in faster and more accurate identifications.

Case study: calmodulin in section *Nigri*

Partial calmodulin gene sequences of about 1500 strains of *Aspergillus* section *Nigri*, previously amplified and aligned using the software package BioNumerics 5.1 (Applied Maths) with manual adjustments as necessary, were subjected to homology screening using the same software to assemble a reduced data set representative of the entire population of sequenced strains. This reduced panel of 129 DNA sequences, representative for the known diversity among 1438 strains of section *Nigri*, were aligned by Clustal W (Thompson *et al.* 1994) using MEGA version 5 (Tamura *et al.* 2011) and analysed to generate phylogenetic trees in MEGA version 5 (Fig. 3). Both the Neighbor-Joining (NJ) method (Saitou & Nei 1987) and the Maximum Likelihood (ML) method based on the Tamura-Nei model (Tamura & Nei 1993) were used. The analyses confirmed the existence of 25 well defined species clades in section *Nigri*. The aligned data set was exported to FASTA format for analysis of sequence diversity and polymorphism using the DnaSP v5 software (Librado & Rozas 2009). The software generated a haplotype data file that demonstrated the presence of 70 different haplotypes (see below) among the 129 representative strains, with the number of aligned sites in the complete data file being 536, with 188 single-nucleotide polymorphisms (SNPs) detected. An assembly of the 188 SNPs generated as a NEXUS file permitted a comparison of the differences in each haplotype, to identify fixed SNPs for each species of section *Nigri*. The analysis and comparison of these SNPs led to the identification of the following polymorphic nucleotides conserved at the species level, identified by their relative position in the full 536 bp alignment (included as supplementary material; Fig. S3):

SNPs fixed for *Aspergillus* section *Nigri* uniseriate species (nucleotide position and letter):

76 T, 81 A, 84 C, 115 T, 116 A, 179 A, 225 T, 249 A, 252 A, 268 T, 387 A, 411 T, 417 T, 420 C, 429 G

SNPs fixed for *Aspergillus* section *Nigri* biseriate species (nucleotide position and letter):

84 T, 115 G, 116 G, 179 G, 249 C, 252 G, 268 C, 411 C, 420 T, 429 A

SNPs fixed for *A. niger/welwitschiae* complex species (nucleotide position and letter):

64 G, 91 T, 291 T, 381 T

SNPs fixed for *A. welwitschiae* in respect to *A. niger* (nucleotide position and letter):

202 T, 209 T, 519 T

Specific SNPs unique or combination of position for the different species (nucleotide position and letter):

A. brasiliensis: 80-81-82 A-C-C, 181 A, 236 G.

A. costaricensis: 316 G.

A. carbonarius: 78 A, 236 A, 404-405 A-A, 413-414 A-A.

A. ellipticus: 80 T, 412 T, 74-75-76-77 G-G-G-G.

A. floricola: 128 C, 383 C.

A. heteromorphus: 79 C, 80 C, 89-91 T-A, 232-233 C-T, 206-208-209 T-A-A, 216-217-218 A-C-C.

A. homomorphus: 223 C, 238 C, 403 G, 415 G 381-382-383 A-C-G.

A. ibericus: 133 T, 160 T, 218-219 C-T.

A. japonicus: 516 T.

A. luchuensis (= *A. acidus*)/*A. piperis*: 83 T, 137 T, 151 C in *A. luchuensis*, and T in *A. piperis*.

A. saccharolyticus: 185 A, 198 G.

A. sclerotii carbonarius: 108 T, 137 G.

A. sclerotiger: 92 G, 202-203 T-T, 416-417-419 C-A-G.

A. trinidadensis: 261 G.

A. uvarum: 204-205-206-208 C-A-C-T.

A. vadensis: 161 A, 217 T.

A. welwitschiae: 209 T.

The other species not included, such as *A. aculeatinus*, *A. aculeatus*, *A. fijiensis/brunneoviolaceus*, *A. indologenus*, *A. japonicus*, *A. neoniger*, *A. tubingensis*, lacked unique species specific SNPs within the section *Nigri*, but a combination of SNPs differentiates all from closely related sister species:

A. tubingensis/A. neoniger: 204-205-206-222 CATT in *A. neoniger* and CCTA in *A. tubingensis*.

A. japonicus/A. indologenus: 339-342-366-369 CTTC in *A. indologenus* and CCTT in *A. japonicus*.

A. aculeatinus: 158-159-160-161-175-176 CCACAA.

A. aculeatus: 194 T, 342-354-357-360 TTCT.

A. fijiensis/A. brunneoviolaceus: 483-486 CT.

Some combinations of SNPs were identified for a unique and atypical strain of *A. aculeatus* (ITEM 4760 = CBS 620.78), but we cannot determine whether they are species specific or strain specific, or whether this strain available might represent a yet unidentified, distinct species in the *A. aculeatus* clade. The haplotype analysis presented shows *CaM* sequences have fixed SNP's that is unique and specific to species and that the gene is suitable for identifying isolates in the section *Nigri*.

Extrolite data

Isolates of *Aspergillus* species usually produce a diverse range of secondary metabolites that are characteristic of the different groups of sections of *Aspergillus*. For example, isolates of species of *Aspergillus* section *Flavi* nearly all produce kojic acid (Varga *et al.* 2011), while species in other sections produce other small acidic molecules, e.g. penicillic acid by most species of *Aspergillus* section *Circumdati* (Frisvad *et al.* 2004). Specific secondary metabolites are often only found in one section of *Aspergillus*, but some important extrolites, such as ochratoxin A, are produced by species in sections *Flavi*, *Circumdati* and *Nigri* (Frisvad *et al.* 2004, 2011, Varga *et al.* 2011). Production of a particular secondary metabolite is thus an efficient identification aid for allocating a species to section, while several identified secondary metabolites can be very effective in identifying an *Aspergillus* isolate to species. Although polyphasic identification is recommended, secondary metabolite profiles occasionally may be sufficient to identify isolates of *Aspergillus* to species. A qualitative database on the verified production of secondary metabolites by different species of *Aspergillus* is required to enable identification of *Aspergillus* isolates based only on this methodology. Furthermore, growth media and conditions, and analytical procedures must be standardised, but several papers contain recommendations on how to extract, separate and identify secondary metabolites (Nielsen *et al.* 2011a, Kildgaard *et al.* 2014, Klitgaard *et al.* 2014). It is important to note that although normal identification media often yield secondary

Fig. 3. Phylogenetic tree obtained with 188 polymorphic sites and fixed SNPs (conserved in spp.) derived from the calmodulin sequences of strains representative of the genetic variability of the 25 recognised species in *Aspergillus* section *Nigri* (* = type strains).

metabolites, different media may give very different profiles of secondary metabolites (Nielsen *et al.* 2011b).

Misidentifications in *Aspergillus*

It is critical that *Aspergillus* isolates used for reports of new or interesting extrolites be properly identified. Unfortunately, many strains continue to be misidentified, resulting in chemical data that is linked to an incorrect species name. More seriously, when regulated mycotoxins such as ochratoxin A or aflatoxin are attributed to misidentified species, regulatory officials may include the incorrect names in quarantine legislation, or initiate food-safety recalls based on scientifically inaccurate information. An early example of the misattribution of toxins to a species involved an entomogenous strain of *A. flavus* that infected pupa of a wax moth, and was reported to produce asperflavin, anhydroasperflavin, the mycophenolic acid precursor 5,6-dihydroxy-4-methylphthalide and asperentins (Grove 1972a,b, 1973). The strain was explicitly reported not to produce aflatoxins, and chemical data indicate that the strain was *A. pseudoglaucus* (formerly *Eurotium repens*). A recent example is a strain identified as *Aspergillus sydowii* (PFW1, strain unavailable) that was reported to produce 17 secondary metabolites from different biosynthetic families (Zhang *et al.* 2008) that are typical of *A. fumigatus* (Frisvad *et al.* 2009); the culture was probably a typical *A. fumigatus* strain. Similarly, a fungus identified as *A. varicolor* (B-17, strain unavailable) produced 23 metabolites (Wang *et al.* 2007) all typical of *Aspergillus* section *Aspergillus*. The fungus was reported as halotolerant, and was most probably a species with a *Eurotium*-like sexual state, but the new metabolites were unfortunately all named after *A. varicolor* (varicolorins A-L).

In some cases, these problems were caused by mixed or contaminated cultures. For example, a series of *A. niger* extrolites (Nielsen *et al.* 2009) were reported from *Cladosporium herbarum* (Ye *et al.* 2005) and *Pestalotiopsis theae* (Ding *et al.* 2008). Although the original cultures may have been correctly identified (unfortunately, they were not deposited in a culture collection), these strains were obviously contaminated with black aspergilli, because the metabolites that were structurally elucidated or identified have never been otherwise attributed to any *Cladosporium* or *Pestalotiopsis* species. In the latter case involving isolates from tea, the metabolites were named after the *Pestalotiopsis* (pestalazines and pestalamides), but they are probably just metabolites of *A. luchuensis*, a species also found on tea (Hong *et al.* 2013). Similarly, strains of *Chaetomium globosum* (Wang *et al.* 2006) and *Microascus tardifaciens* (Fujimoto *et al.* 1999) were reported to produce a series of *Aspergillus* extrolites typical of species formerly classified in *Eurotium*, but were probably either misidentified or the cultures were mixed.

Matrix-assisted laser desorption/ionization time-of-flight mass spectrometry fingerprinting (MALDI-TOF MS)

Matrix-assisted laser desorption/ionization time-of-flight mass spectrometry fingerprinting (MALDI-TOF MS) is fast becoming an important tool for species identification in the medical field, having been successfully applied to bacteria (Hettick *et al.* 2006, Siegrist *et al.* 2007) and yeasts (Amiri-Eliasi & Fenselau 2001, Kolečka *et al.* 2013). The medical importance of various

Aspergillus species causing aspergillosis, most notably *A. fumigatus*, has led to a few studies testing MALDI-TOF as an identification tool. As with MALDI-TOF experiments on the closely related *Penicillium* (Welham *et al.* 2000, Hettick *et al.* 2008, Del Chierico *et al.* 2012, Chalupová *et al.* 2014), results seem promising (Bille *et al.* 2011, De Carolis *et al.* 2011, Iriart *et al.* 2012, Verwer *et al.* 2013). For example, De Carolis *et al.* (2011) showed that MALDI-TOF successfully distinguished between the closely related *A. fumigatus* and *A. lentulus*. In all of these studies, wide variation is observed in spectra of different strains of the same species, with Hettick *et al.* (2008) also reporting variation between duplicates of the same *Penicillium* strain. However, in most cases, spectra from the same species cluster together, meaning that the database should be expanded to include as many strains as possible to increase identification accuracy.

TAXONOMY

Following the phylogenetic study by Houbraken & Samson (2011), the type species of *Polypaecilum* and *Phialosimplex* were shown to be related to members of sections *Cremeri* and *Aspergillus*, placing those genera within *Aspergillus*. Varga *et al.* (2007a) showed that *Dichotomomyces*, which also has a *Polypaecilum*-like asexual state, is closely related to sections *Fumigati* and *Clavati*, and proposed the synonymy of this genus with *Aspergillus*.

The relationship of *Penicillium inflatum* with other members of the *Aspergillaceae* was studied by combining the *RPB2*, *Cct8* and *Tsr1* data sets (Fig. 4). Statistical support was measured by Maximum Likelihood (ML) analysis using the RAXML (randomised accelerated maximum likelihood) software (Stamatakis 2014) and by Bayesian tree inference (BI) analysis using MrBayes v3.1.2 (Ronquist & Huelsenbeck 2003). Prior to the analysis, the most suitable substitution model was determined using MrModeltest 2.3 (Nylander *et al.* 2004), utilising the Akaike Information Criterion (AIC). The phylogeny shows that *P. inflatum* belongs to *Aspergillus* section *Cremeri* (Gams *et al.* 1985; Fig. 4). This section (the *A. cremeri* species group of Raper & Fennell 1965) includes species with colonies in shades of yellowish brown to brown or grey green, biserial conidial heads and long conidiophores. Peterson (1995, 2000) studied section *Cremeri* in detail and transferred several species to this section based on molecular evidence, including *A. wentii* (from section *Wentii*), *A. dimorphicus* (from section *Circumdati*), *A. gorakhpurensis* and *A. pulvinus* (from section *Versicolores*). Later, Varga *et al.* (2000) also transferred *A. sepultus* to this section. Recently, Peterson (2008) found that *A. brunneouniseriatus* (previously assigned to section *Ornati*) also belongs to section *Cremeri*, although supported only by low bootstrap values and Bayesian posterior probabilities. The species assigned to this section are economically less important, with the exception of *A. wentii*, which is a source of enzymes, and frequently included in 'koji' (Raper & Fennell 1965, Lowe 1992).

When Stolk & Malla (1971) described *P. inflatum*, they speculated that the swollen apices of its conidiophores and strongly diverging metulae might suggest that the species belongs in *Aspergillus*. They decided to place it in *Penicillium* because of the lack of a foot-cell, its thin conidiophore walls and the fact that its metulae did not develop simultaneously. *Penicillium inflatum* was reported to produce sterigmatocystin (Rank *et al.* 2011),

Fig. 4. Combined phylogeny of the *RPB2*, *Cct8* and *Tsr1* gene regions showing the phylogenetic position of *P. inflatum* ($\equiv$ *A. inflatus*) in *Aspergillus* sect. *Cremeri*. The tree was rooted to *Talaromyces flavus*. Branches with bootstrap support above 80 % and/or posterior probability above 0.95 are given above thickened branches.

confirmed for all strains of *P. inflatum* in the present study, with three of the strains also producing patulin or its precursor 6-methylsalicylic acid. Patulin occurs in species in *Aspergillus*, *Penicillium* and *Byssosclamyces*, but sterigmatocystin is restricted

to species in four different sections in *Aspergillus* (*Ochraceorosei*, *Versicolores*, *Nidulantes* and *Flavi*) and has never been found in *Penicillium sensu stricto*. Chemotaxonomic evidence thus supports that *P. inflatum* should be transferred to *Aspergillus*.

Among the species formerly ascribed to *Phialosimplex*, *Polypaecilum* and *Basipetospora*, two of these are halophilic and like other halophilic species do not produce many extrolites (Frisvad 2005). No traceable extrolites were found in *Basipetospora halophila* and *Polypaecilum pisci*. *Phialosimplex chlamydosporus* did not produce any extrolites under the conditions tested, while *Phialosimplex sclerotialis* and *Polypaecilum insolitum* each produced only what appeared to be unique extrolites for those species, preventing any chemotaxonomic comparison with other *Aspergillus* species. However, *Phialosimplex caninus* produced asteric acid, erdin and sulochrin, extrolites found in *Aspergillus terreus* (Samson et al. 2011), *Penicillium glabrum* (as *P. frequentans*) (Mahmoodian & Stickings, 1964) and *P. estinogenum*.

Houbraken & Samson (2011) found that the type species of *Cristaspora*, *C. arxii*, formed a well-supported clade with members of section *Cremeri* (*A. pulvinus*, *A. wentii*, *A. brunneouniseriatus*) and that this clade is more closely related to members of the subgenus *Aspergillus* than to subgenus *Circumdati*. The transfer of *C. arxii* is therefore proposed below. *Cristaspora arxii* shares the production of rubratoxins together with *Aspergillus* (*Dichotomomyces*) *cejpai* (Varga et al. 2007a) and *Talaromyces purpurogenus* (Yilmaz et al. 2012). Rubratoxins are not produced by species of *Penicillium*.

By including genera and species with morphological structures deviating from the typical aspergillum, the generic concept should be emended to the following polythetic description:

***Aspergillus* P. Micheli ex Haller, emended description**

Generic type: *Aspergillus glaucus* (L.) Link

Vegetative mycelium hyaline to brightly pigmented. Conidiophores (aspergillum) consisting of thick-walled basal cells (foot cell) producing stalks, usually aseptate and unbranched, terminating in inflated apex (vesicle) which can be globose, ellipsoidal to clavate; conidiophores in some species may be septate, lack a foot cell, lack a vesicle, or consisting of single conidiogenous cells with one to several loci. Conidiogenous cells phialidic, producing dry conidial chains borne directly on the vesicle (uniseriate) or on metulae (biseriate); in a few species, appearing to be annellidic or polyphialidic. Conidia greatly varying in colour, size, shape and ornamentation. Cleistothecia of various structures produced by some species with mostly a thin ascoma wall consisting of a single layer of hyphal networks, sometimes covered by layers of Hülle cells or sclerotium-like. Asci globose usually containing eight ascospores. Ascospores often lenticular, hyaline or coloured, varying in size, shape and ornamentation. Sclerotia or sclerotium-like structures regularly present in some species, varying in colour, size and shape, consisting of thick-walled cells, sometimes containing ascigerous structures. Hülle cells sometimes covering cleistothecia or occurring in compact masses in the mycelium, varying in shape and size, but mostly thick-walled and hyaline.

The following new combinations and new names are proposed:

Aspergillus arxii (Fort & Guarro) Houbraken, Visagie & Samson, **comb. nov.** MycoBank MB809575.

Basionym: *Cristaspora arxii* Fort & Guarro, Mycologia 76: 1115. 1984.

Typus: CBS H-14047, culture ex-type CBS 525.83 = ATCC 52744 = FMR 416.

Aspergillus assulatus (S.B. Hong, Frisvad & Samson) Houbraken, Visagie & Samson, **comb. nov.** MycoBank MB809576. *Basionym:* *Neosartorya assulata* S.B. Hong, Frisvad & Samson, Antonie van Leeuwenhoek 93: 95. 2008.

Typus: KACC 41691, culture ex-type KACC 41691 = IBT 27911.

Aspergillus astellatus (Fennell & Raper) Houbraken, Visagie & Samson, **comb. nov.** MycoBank MB809577.

Basionym: *Aspergillus variegatus* var. *astellatus* Fennell & Raper, Mycologia 47: 81. 1955.

= *Emericella astellata* (Fennell & Raper) Y. Horie, Trans. Mycol. Soc. Japan 21: 491. 1980.

Typus: IMI 061455, culture ex-type CBS 134.55 = CBS 261.93 = NRRL 2396 = ATCC 16817 = IMI 61455 = IMI 61455ii = NRRL A-1634 = QM 1910 = WB 2396.

Aspergillus australensis (Samson, S.B. Hong & Varga) Houbraken, Visagie & Samson, **comb. nov.** MycoBank MB809578. *Basionym:* *Neosartorya australensis* Samson, S.B. Hong & Varga, Stud. Mycol. 59: 174. 2007.

Typus: CBS 112.55, culture ex-type CBS 112.55 = NRRL 2392 = IMI 061450.

Aspergillus baarnensis Samson, Visagie & Houbraken, **nom. nov.** MycoBank MB809579.

Basionym: *Oospora halophila* J.F.H. Beyma, Zentralbl. Bakteriologie. Parasitenk., Abt. 2 88: 134. 1933.

= *Basipetospora halophila* (J.F.H. Beyma) Pitt & A.D. Hocking, Mycotaxon 22: 198. 1985.

= *Scopulariopsis halophilica* Tubaki, Trans. Mycol. Soc. Japan 14: 367. 1973.

Typus: CBS 232.32, culture ex-type: CBS 232.32 = VKM F-204.

Etymology: Latin, *baarnensis*, named after the city of Baarn, the Netherlands, the original home of CBS where *Oospora halophila* was discovered.

Note: Non *Aspergillus halophilus* Sartory, R. Sartory & J. Mey., Ann. Mycol. 28: 362. 1930. Non *Aspergillus halophilicus* C.M. Chr. et al., Mycologia 51: 636. 1961. With the names *A. halophilus* and *A. halophilicus* already being occupied, the new name is proposed.

Aspergillus caninus (Sigler, Deanna A. Sutton, Gibas, Summerb. & Iwen) Houbraken, Tanney, Visagie & Samson, **comb. nov.** MycoBank MB809580.

Basionym: *Phialosimplex caninus* Sigler, Deanna A. Sutton, Gibas, Summerb. & Iwen, Med. Mycol. 48: 338. 2010.

Typus: UAMH 10337, culture ex-type CBS 128032 = UAMH 10337.

Aspergillus capsici (J.F.H. Beyma) Houbraken, Visagie & Samson, **comb. nov.** MycoBank MB809581.

Basionym: *Scopulariopsis capsici* J.F.H. Beyma, Antonie van Leeuwenhoek 10: 50. 1945.

= *Polypaecilum capsici* (J.F.H. Beyma) G. Sm., Trans. Brit. Mycol. Soc. 44: 439. 1961.

Typus: CBS 176.44, culture ex-type CBS 176.44 = IMI 086564 = LSHB BB423 = QM 7962.

Aspergillus cejpaii (Milko) Samson, Varga, Visagie & Houbraken, **comb. nov.** MycoBank MB809582.

Basionym: *Talaromyces cejpaii* Milko, Novosti Sist. Nizsh. Rast. 1: 208. 1964.

≡ *Dichotomomyces cejpaii* (Milko) D.B. Scott, Trans. Brit. Mycol. Soc. 47: 428. 1970.

Typus: CBS H-7011, culture ex-type CBS 157.66.

Aspergillus chinensis Samson, Visagie & Houbraken, **nom. nov.** MycoBank MB809583.

Basionym: *Emericella appendiculata* Y. Horie & D.M. Li, Mycoscience 39: 161. 1998.

Typus: CBM FA-865, culture ex-type CBS 128791 = IFM 54282 = CBM FA-865.

Etymology: Latin, *chinensis*, named in reference to the type originating from China.

Note: Non *Aspergillus appendiculatus* Blaser, Sydowia 28: 38. 1975. The name *A. appendiculatus* is already occupied and therefore the new name is proposed.

Aspergillus chlamydosporus (Gené & Guarro) Houbraken, Tanney, Visagie & Samson, **comb. nov.** MycoBank MB809584.

Basionym: *Sagenomella chlamydospora* Gené & Guarro, J. Clin. Microbiol. 41: 1723. 2003.

≡ *Phialosimplex chlamydosporus* (Gené & Guarro) Sigler, Med. Mycol. 48: 341. 2010.

Typus: IMI 387422, culture ex-type CBS 109945 = IMI 387422 = FMR 7371.

Aspergillus delacroixii Samson, Visagie & Houbraken, **nom. nov.** MycoBank MB809585.

Basionym: *Aspergillus nidulans* var. *echinulatus* Fennell & Raper, Mycologia 47: 79. 1955.

≡ *Emericella nidulans* var. *echinulata* (Fennell & Raper) Godeas, Mycopathol. Mycol. Appl. 46: 193. 1972.

≡ *Emericella echinulata* (Fennell & Raper) Y. Horie, Trans. Mycol. Soc. Japan 21: 492. 1980.

Typus: IMI 061454, culture ex-type CBS 120.55 = NRRL 2395 = ATCC 16825 = IMI 061454 = LCP 84.2557 = QM 1909 = WB 2395.

Etymology: Latin, *delacroixii*, named after Edouard Georges Delacroix (1858–1907).

Note: Non *Aspergillus echinulatus* (Delacr.) Thom & Church, The Aspergilli: 107. 1926. The name *A. echinulatus* is already occupied and therefore the new name is proposed.

Aspergillus denticulatus (Samson, S.B. Hong & Frisvad) Samson, S.B. Hong, Visagie & Houbraken, **comb. nov.** MycoBank MB809586.

Basionym: *Neosartorya denticulata* Samson, S.B. Hong & Frisvad, Antonie van Leeuwenhoek 93: 95. 2008.

Typus: CBS 652.73, culture ex-type CBS 652.73 = KACC 41183.

Aspergillus desertorum (Samson & Mouch.) Samson, Visagie & Houbraken, **comb. nov.** MycoBank MB809587.

Basionym: *Emericella desertorum* Samson & Mouch., Antonie van Leeuwenhoek 40: 121. 1974.

Typus: CBS H-7045, culture ex-type CBS 653.73 = NRRL 5921 = IMI 343076.

Aspergillus ferenczii (Varga & Samson) Samson, Varga, Visagie & Houbraken, **comb. nov.** MycoBank MB809588.

Basionym: *Neosartorya ferenczii* Varga & Samson, Stud. Mycol. 59: 178. 2007.

Typus: CBS 121594, culture ex-type CBS 121594 = NRRL 4179 = IBT 27813 = DTO24F2.

Aspergillus galapagensis (Frisvad, S.B. Hong & Samson) Samson, Frisvad & Houbraken, **comb. nov.** MycoBank MB809589.

Basionym: *Neosartorya galapagensis* Frisvad, S.B. Hong & Samson, Antonie van Leeuwenhoek 93: 96. 2008.

Typus: CBS 117522, culture ex-type CBS 117522 = IBT 16756 = KACC 41935 = DTO3H4.

Aspergillus inflatus (Stolk & Malla) Samson, Frisvad, Varga, Visagie & Houbraken, **comb. nov.** MycoBank MB809590. Fig. 5.

Basionym: *Penicillium inflatum* Stolk & Malla, Persoonia 6: 197. 1971.

Typus: CBS H-7500, culture ex-type CBS 682.70 = FRR 1549 = IMI 191498.

Aspergillus insolitus (G. Sm.) Houbraken, Visagie & Samson, **comb. nov.** MycoBank MB809591.

Basionym: *Polypaecilum insolitum* G. Sm., Trans. Brit. Mycol. Soc. 44: 437. 1961.

Typus: CBS 384.61, culture ex-type CBS 384.61 = ATCC 18164 = IFO 8788 = IMI 075202 = LSHB BB414 = MUCL 3078 = QM 7961.

Aspergillus jaipurensis Samson, Visagie & Houbraken, **nom. nov.** MycoBank MB809592.

Basionym: *Emericella indica* Stchigel & Guarro, Mycol. Res. 103: 1059. 1999.

Typus: IMI 378525, culture ex-type IMI 378525.

Etymology: Latin, *jaipurensis*, named after the city Jaipur in India, the origin of the type strain.

Note: Non *Aspergillus indicus* B.S. Mehrotra & Agnihotri, Mycologia 54: 403. 1963. The name *A. indicus* is already occupied and therefore the new name is proposed.

Aspergillus papuensis (Samson, S.B. Hong & Varga) Samson, S.B. Hong & Varga, **comb. nov.** MycoBank MB809593.

Basionym: *Neosartorya papuensis* Samson, S.B. Hong & Varga, Stud. Mycol. 59: 190. 2007.

Typus: CBS H-6277, culture ex-type CBS 841.96 = IBT 27801.

Aspergillus pisci (A.D. Hocking & Pitt) Houbraken, Visagie & Samson, **comb. nov.** MycoBank MB809594.

Basionym: *Polypaecilum pisci* A.D. Hocking & Pitt, [as 'pisce'] Mycotaxon 22: 200. 1985.

Typus: FRR 2732, culture ex-type FRR 2732 = ATCC 56982 = IMI 288726.

Aspergillus pluriseminatus (Stchigel & Guarro) Samson, Visagie & Houbraken, **comb. nov.** MycoBank MB809595.

Basionym: *Emericella pluriseminata* Stchigel & Guarro, Mycologia 89: 937. 1997.

Typus: FMR 5588 (isotype IMI 370867), culture ex-type CBS 100523 = FMR 5588 = IMI 370867.

Fig. 5. *Aspergillus inflatus*. A. Colonies on CYA. B. Colonies on MEA. C. Colonies on CREA. D–H. Conidiophores. I. Conidia. Scale bars: D–I = 10 µm.

Aspergillus sclerotialis (W. Gams & Breton) Houbraken, Tanney, Visagie & Samson, **comb. nov.** MycoBank MB809596. *Basionym*: *Sagenomella sclerotialis* W. Gams & Breton, Persoonia 10: 109. 1978.

≡ *Phialosimplex sclerotialis* (W. Gams & Breton) Sigler, Med. Mycol. 48: 341. 2010.

Typus: CBS 366.77, culture ex-type CBS 366.77 = IAM 14794.

Aspergillus shendawei (Yaguchi, Abliz & Y. Horie) Samson, Visagie & Houbraken, **comb. nov.** MycoBank MB809597.

Basionym: *Neosartorya shendawei* Yaguchi, Abliz & Y. Horie, Mycoscience 51: 260. 2010.

Typus: CBM FA-0958, culture ex-type IFM 57611.

Aspergillus similis (Y. Horie, Udagawa, Abdullah & Al-Bader) Samson, Visagie & Houbraken, **comb. nov.** MycoBank MB809598.

Basionym: *Emericella similis* Y. Horie, Udagawa, Abdullah & Al-Bader, Trans. Mycol. Soc. Japan 31: 425. 1990.

Typus: CBM 10007, culture ex-type CBS 293.93 = NHL 3000.

Aspergillus solicola Samson, Visagie & Houbraken, **nom. nov.** MycoBank MB809599.

Basionym: *Neosartorya warcupii* Peterson, Varga & Samson, Stud. Mycol. 59: 201. 2007.

Typus: NRRL 35723, culture ex-type NRRL 35723.

Etymology: Latin, *solicola*, meaning soil inhabitant, in reference to the type strain that was isolated from soil.

Note: Non *Aspergillus warcupii* Samson & W. Gams, Adv. *Penicillium Aspergillus* Syst.: 50. 1985. The name *A. warcupii* is already occupied and therefore the new name is proposed.

Aspergillus tsunodae (Yaguchi, Abliz & Y. Horie) Samson, Visagie & Houbraken, **comb. nov.** MycoBank MB809600.

Basionym: *Neosartorya tsunodae* Yaguchi, Abliz & Y. Horie, Mycoscience 51: 261. 2010.

Typus: CBM FA-0950, culture ex-type IFM 57609 = NBRC 106416.

Proposed list of accepted *Aspergillus* names

The following list includes species accepted in the genus *Aspergillus* and is updated from Pitt & Samson (1993) and Pitt *et al.* (2000). Noticeable changes from the previous lists are the incorporation of *Aspergillus* names for species previously accepted in the associated teleomorphic genera, as well as species previously classified in *Cristaspora*, *Dichotomomyces*, *Basipetospora*, *Phialosimplex* and *Polypaecilum* as well as *Penicillium inflatum*. The nomenclatural list includes MycoBank numbers, collection numbers of type and ex-type cultures and GenBank accession numbers to ITS barcodes and alternative identification markers *BenA*, *CaM* and *RPB2*. Similar lists are published for *Penicillium* (Visagie *et al.* 2014a) and *Talaromyces* (Yilmaz *et al.* 2014).

A considerable amount of time and effort was spent on having the list as complete as possible. However, we acknowledge that there might be some mistakes in this list. As such, we gratefully accept any comments on missing names, errors, new data that has become available, or on methods to make the list more

functional. As the taxonomy keeps evolving in fungi, this list will be kept up to date on <http://www.aspergilluspenicillium.org> from where comments can be sent to curators of the list. The website also lists currently considered synonym names and is not included in the list below.

Aspergillus P. Micheli ex Haller, Hist. Stirp. Helv.: 113. 1768. MycoBank MB7248.

≡ *Aspergillus* P. Micheli, Nov. Pl. Gen.: 212, t. 92.1729. [MB39019]. anamorphic synonym.

(Alternative markers: *BenA* = EF652106; *CaM* = EF652131; *RPB2* = EF652092).
- Aspergillus westerdijkiae*** Frisvad & Samson, *Stud. Mycol.* 50: 30. 2004. [MB500000]. — Herb.: CBS H-13444. Ex-type: CBS 112803 = NRRL 3174 = IBT 10738 = ATCC 22947 = IBT 10738 = MUCL 39539. ITS barcode: EF661427. (Alternative markers: *BenA* = EF661329; *CaM* = EF661360; *RPB2* = EF661307).
- Aspergillus westlandensis*** Visagie *et al.*, *Stud. Mycol.* 78: 59. 2014. [MB809204]. — Herb.: CBS H-21795. Ex-type: CBS 137321 = IBT 32139 = DTO 231-A9. ITS barcode: KJ775434. (Alternative markers: *BenA* = KJ775066; *CaM* = KJ775230; *RPB2* = n.a.).
- Aspergillus wyomingensis*** A. Nováková, Dudová & Hubka, *Fungal Divers.* 64: 270. 2014. [MB803936]. — Herb.: PRM 861504. Ex-type: CCF 4417 = CMF ISB 2494. ITS barcode: HG324081. (Alternative markers: *BenA* = HF933359; *CaM* = HF933397; *RPB2* = HF937378).
- Aspergillus xerophilus*** Samson & Mouch., *Antonie van Leeuwenhoek* 41: 348. 1975 ≡ *Eurotium xerophilum* Samson & Mouch., *Antonie van Leeuwenhoek* 41: 348. 1975. [MB309251]. — Herb.: CBS 938.73. Ex-type: CBS 938.73 = NRRL 6131. ITS barcode: EF652085. (Alternative markers: *BenA* = EF651923; *CaM* = EF651983; *RPB2* = EF651970).

Excluded and doubtful species

- Aspergillus amazonensis* (Henn.) Samson & Seifert, *Adv. Penicillium Aspergillus Syst.*: 418. 1985 ≡ *Stilbothamnium amazonense* Henn., *Hedwigia* 43: 396. 1904. [MB114696]. — Herb.: Brazil, Jurna, Jul 1907, Ule in herb. Hennings (S). Ex-type: unknown. ITS barcode: n.a. (Alternative markers: *BenA* = n.a.; *CaM* = n.a.; *RPB2* = n.a.). Note: Apart from herbarium material, there is no ex-type culture or sequences available. As such, we cannot confirm the taxonomic position of the species.
- Aspergillus clavatoflavus* Raper & Fennell, *Gen. Aspergillus*: 378. 1965. [MB326619]. — Herb.: IMI 124937. Ex-type: CBS 473.65 = NRRL 5113 = ATCC 16866 = IMI 124937 = QM 8877 = WB 5113. Note: Molecular data suggest that this species does not belong to *Aspergillus* (Peterson 2008, Houbraken & Samson 2011).
- Aspergillus collembolorum* Dörfelt & A.R. Schmidt, *Mycol. Res.* 109: 956. 2005. [MB344420]. — Herb.: Hoffeins 805. Ex-type: unknown. ITS barcode: n.a. (Alternative markers: *BenA* = n.a.; *CaM* = n.a.; *RPB2* = n.a.). Note: Apart from herbarium material, there is no ex-type culture or sequences available. As such, we cannot confirm the taxonomic position of the species.
- Aspergillus curviformis* H.J. Chowdhery & J.N. Rai, *Nova Hedwigia* 32: 231. 1980. [MB118396]. — Herb.: [dried culture from soil from] India, Kagh Islands, s.coll. (LWG). Ex-type: unknown. ITS barcode: n.a. (Alternative markers: *BenA* = n.a.; *CaM* = n.a.; *RPB2* = n.a.). Note: Apart from the location of the herbarium specimen, there is no information available with regards to ex-type cultures or sequences. As such, we cannot confirm the taxonomic position of the species.
- Aspergillus dybowskii* (Pat.) Samson & Seifert, *Adv. Penicillium Aspergillus Syst.*: 422. 1985 ≡ *Penicillioptis dybowskii* Pat., *Bull. Soc. Mycol. Fr.* 8: 54. 1892. [MB114702]. — Herb.: Congo, Jan 1894, Dybowski in herb. Bresadola (S). Ex-type: unknown. ITS barcode: n.a. (Alternative markers: *BenA* = n.a.; *CaM* = n.a.; *RPB2* = n.a.). Note: Apart from herbarium material, there is no ex-type culture or sequences available. As such, we cannot confirm the taxonomic position of the species.
- Aspergillus erythrocephalus* Berk. & M.A. Curtis, *J. Linn. Soc. Bot.* 10: 362. 1868. [MB212597]. — Herb.: Cuba, Wright 764 (K). Ex-type: unknown. ITS barcode: n.a. (Alternative markers: *BenA* = n.a.; *CaM* = n.a.; *RPB2* = n.a.). Note: Apart from herbarium material, there is no ex-type culture or sequences available. As such, we cannot confirm the taxonomic position of the species.
- Aspergillus globosus* H.J. Chowdhery & J.N. Rai, *Nova Hedwigia* 32: 233. 1980 (*nom. illegit.*, Art. 53.3). [MB118398]. — Herb.: [dried culture from soil from] India, Kagh Islands, s.coll. (LWG). Ex-type: unknown. ITS barcode: n.a. (Alternative markers: *BenA* = n.a.; *CaM* = n.a.; *RPB2* = n.a.). Note: *Aspergillus globosus* Link is the older name for the epithet and thus makes this an illegitimate name under Art. 53.3. Apart from the designation of a herbarium specimen, there is no information available with regards to ex-type cultures or sequences. As such, we cannot confirm the taxonomic position of the species.
- Aspergillus ornatus* Samson & W. Gams, *Adv. Penicillium Aspergillus Syst.*: 45. 1985 ≡ *Sclerocleista ornata* (Raper, Fennell & Tresner) Subram., *Current Science* 41: 757. 1972. [MB114712]. — Herb.: IMI 55295. Ex-type: CBS

124.53 = NRRL 2256 = ATCC 16921 = IMI 55295 = LSHBBB .311 = MUCL 15643 = NRRL A-3471 = QM 1951 = UC4518 = WB 2256. Note: Molecular data suggest that this species belongs to a clade distinct from *Aspergillus* (Houbraken & Samson 2011).

Aspergillus spinulosus Warcup, Gen. *Aspergillus*: 204. 1965 = *Raperia spinulosa* (Warcup) Subram. & Rajendran, Kavaka 3: 133. 1976 = *Warcupia spinulosa* (Warcup) Subram., Curr. Sci. 41: 757. 1972 = *Aspergillus warcupii* Samson & W. Gams, Adv. *Penicillium Aspergillus* Syst.: 50. 1985. [MB326657]. — Herb.: IMI 75885. Ex-type: CBS 512.65 = NRRL 4376 = A41/4 = ATCC 16919 = IFO 31800 = IMI 238611 = IMI 75885 = IMI 75885ii = IMI 75885iii = IMI 75885iv = QM 7858 = WB 4376. ITS barcode: EF669706. (Alternative markers: *BenA* = EF669680; *CaM* = EF669698; *RPB2* = EF669666). Note: Molecular data showed that this species belongs in a phylogenetic clade with *Hamigera*.

Aspergillus taklimakanensis Abliz & Y. Horie, Mycoscience 42: 289. 2001 = *Eurotium taklimakanense* Abliz & Y. Horie, Mycoscience 42: 289. 2001. [MB474683]. — Herb.: CBM FA-876. Ex-type: CBM FA-876 = Y. Horie No. 98-TA-571-C. Note: The ex-type culture no longer exist. As such we cannot confirm its taxonomic position and consider it a doubtful species.

Aspergillus vitellinus (Massee) Samson & Seifert, Adv. *Penicillium Aspergillus* Syst.: 417. 1985 = *Sterigmatocystis vitellina* Ridl. ex Massee, J. Bot. 34: 152. 1896. [MB114721]. — Herb.: Singapore, 1894, Ridley 2970 (K). Ex-type: unknown. ITS barcode: n.a. (Alternative markers: *BenA* = n.a.; *CaM* = n.a.; *RPB2* = n.a.). Note: Apart from herbarium material, there is no ex-type culture or sequences available. As such, we cannot confirm the taxonomic position of the species.

Aspergillus zonatus Kwon-Chung & Fennell, Raper & Fennell, Gen. *Aspergillus*: 377. 1965. [MB326666]. — Herb.: CBS 506.65. Ex-type: CBS 506.65 = NRRL 5079 = ATCC 16867 = IFO 8817 = IMI 124936 = NRRL 25543 = QM 8919 = WB 5079. ITS barcode: EF669712. (Alternative markers: *BenA* = EF669679; *RPB2* = EF669665; *CaM* = EF669701). Note: Molecular data suggest that this species does not belong to *Aspergillus* (Peterson 2008, Houbraken & Samson 2011).

Dactylomyces thermophilus Sopp, Skr. Vidensk.-Selsk. Christiana Math.-Nat. Kl. 11: 35. 1912 = *Penicillium thermophilum* (Sopp) Sacc., Sylloge Fungorum 25: 671. 1931 = *Thermoascus thermophilus* (Sopp) Arx, The genera of fungi sporulating in pure culture: 94. 1974. [MB224271]. — Herb.: CBS H-18805. Ex-type: CBS 528.71 = BDUN 394 = IMI 123298 = NRRL 5208 = ATCC 26413. Note: Non *Talaromyces thermophilus* Stolk. The genus *Dactylomyces* was introduced for the ascoma producing *D. thermophilus*. This species also produces an anamorph that resembles *Polypaecilum* (Apinis 1967, Stchigel & Guarro 2007). Phylogenetically this species, however, belongs in *Thermoascus* (Houbraken & Samson 2011) and is thus unrelated to *Aspergillus*.

Eurotium amstelodami L. Mangin, Ann. Sci. Nat., Bot., sér. 9 10: 360. 1908. [MB238336]. — Herb.: unknown. Ex-type: unknown. Note: Hubka et al. (2013a,b) showed that neotypification of this species by Samson & Gams (1985) and Pitt & Samson (1993) was based on an erroneous species concept of *Eurotium amstelodami* and its anamorph name *Aspergillus amstelodami*.

Polypaecilum botryoides (F.T. Brooks & Hansf.) V. Rao & de Hoog, Persoonia 8: 202. 1975 = *Torula botryoides* F.T. Brooks & Hansf., Trans. Brit. Mycol. Soc. 8: 134. 1923 (nom. illegit., Art. 53.1). [MB320881]. — Herb.: CBS 143.23. Ex-type: CBS 143.23 = MUCL 7919. ITS barcode: n.a. (Alternative markers: *BenA* = n.a.; *CaM* = n.a.; *RPB2* = n.a.). Note: The ex type culture is available but has not been sequenced. As such, its taxonomic position is unclear and needs further studies.

Polypaecilum thermophilum Dong M. Wang & D.C. Li, J. Fungal Res. 2: 47. 2004. [MB542322]. — Herb.: HSAUP <sub>(03)>80011. Ex-type: unknown. Note: Apart from the designation of a herbarium specimen, there is no information available with regards to ex-type culture or sequences. As such, we cannot confirm the taxonomic position of the species and consider it doubtful.

ACKNOWLEDGEMENTS

This paper was initiated by and formed part of grants from the Alfred P. Sloan Foundation Program on the Microbiology of the Built Environment. The research

of S. Kocsubé and G. Szigeti was supported by the European Union and the State of Hungary, co-financed by the European Social Fund in the framework of TÁMOP 4.2.4.A/2-11-1-2012-0001, National Excellence Program and we acknowledge the Hungarian Research Fund (OTKA K84077) for providing infrastructural and research facilities. We would like to acknowledge Uwe Braun who provided nomenclatural assistance for this manuscript.
