Session Title: Peripheral Vascular Disease State of the Science I
Abstract Category: 34. Vascular - Pathophysiology - Clinical
Presentation Number: 1119-308

Background: Erectile dysfunction (ED) confers an independent risk for cardiovascular (CV) events and total mortality. Aortic pulse wave velocity (PWV) is a predictor of CV events and all-cause mortality. We investigated whether PWV predicts major adverse cardiovascular events (MACE) in ED patients beyond traditional risk factors.

Methods: MACE in relation to PWV were analyzed in 376 patients (mean age 57 y/o).

Results: During a median follow-up of 3.4 years, 33/376 patients (8.8%) experienced a MACE. PWV was associated with MACE and CAD events and the differences between PWV tertiles were significant (figure). Subjects in the highest PWV tertile (>9.2 m/s) had a 4-fold higher risk of MACE compared to those in the lowest tertile (<8.0 m/s, adjusted HR 3.98, P=0.022). The highest tertile was associated with a higher risk of MACE in patients with intermediate Framingham risk score (adjusted HR 3.70, P=0.011), but not in men with high Framingham score. A PWV value of 7.88 m/sec was associated with a negative predictive value (ability to “rule out” MACE) of 96.8%. Addition of PWV to standard risk factors model yielded correct patient reclassification to higher or lower risk category by 16.1% (P=0.001) in the whole cohort and by 8.5% (P=0.0226) in the intermediate risk group.

Conclusion: Higher aortic stiffness is associated with increased risk for a MACE in ED patients. Aortic PWV improves risk prediction when added to standard risk factors and may represent a valuable biomarker of CV risk prediction in these patients.
