Session Title: Non Invasive Imaging: Strain Imaging by Echocardiography
Abstract Category: 17. Non Invasive Imaging: Echo
Presentation Number: 1174-027

Background: Post-systolic shortening (PSS) is myocardial contraction after aortic valve closure and has been proposed as a marker of myocardial ischemia, but its diagnosis is subjective. We determined quantitative threshold of post-systolic strain index (PSI) as a parameter of PSS assessed by 2D speckle tracking transthoracic echocardiogram (TTE) for detection of left ventricular (LV) myocardial ischemic segments assessed by invasive fractional flow reserve (FFR).

Methods: Thirty-four patients (29 male, mean 64.9±12.5 yeas) with 40 coronary arteries with ≥50% stenosis underwent invasive FFR measurements and TTE within 36 days without clinical incident. Apical 4-, 2-, 3-chamber views for longitudinal strain were acquired via TTE; LV segment longitudinal strain thought to be supplied by the coronary vessels was calculated. PSI (%) was calculated as in Figure.

Results: We identified FFR 0.80 in 14 segments. To identify LV segments ± FFR <0.75, the PSI ROC curve had an AUC of 0.632 and best cutoff point of 6% (sensitivity 86.7%, specificity 48%) to distinguish LV segments ± FFR <0.75. To identify LV segments ± FFR ≤0.80, the PSI ROC curve had an AUC of 0.606 and best cutoff point of 12.5% (sensitivity 64.3%, specificity 69.2%).

Conclusion: In stable coronary artery disease subjects with ≥50% coronary artery stenosis, PSI could identify LV segments with FFR <0.75 and ≥0.75 and those with FFR ≤0.80 and >0.80, with thresholds of 6% and 12.5%, respectively.
