Interleukins 33 and 1B serum levels and common carotid arteries remodeling in hypertensive patients with obesity
Oleksii Honchar, Olga Kovalyova
Kharkiv National Medical University, Propeideutics To Internal Medicine
No.1, Kharkiv, Ukraine

Objective: To investigate interrelations between interleukin 33 (IL-33) and IL-1β serum levels and common carotid arteries (CCA) remodeling in hypertensive patients with obesity.

Method: 80 hypertensive patients (51 obese) have been observed. An ultrasound examination of CCA with estimation of its geometrical type was performed (cut-off value for vascular wall hypertrophy was vascular segment mass >0.275 g/cm, concentric remodeling was diagnosed with relative wall thickness of CCA >0.2). IL-33 and IL-1B serum levels were estimated using ELISA.

Results: IL-33 and IL-1B levels were higher in hypertensive patients (p<0.001), independently of BMI. Cluster analysis was made to reveal both cytokines’ levels impact on CCA geometry (see picture). IL-33 ≥73 pg/ml, IL-1β ≥25 pg/ml was associated with 80.0% prevalence of normal CCA geometry and 20.0% of its concentric hypertrophy. IL-1β ≥20 pg/ml with IL-33 ≥71 pg/ml was characterized by 80.0% prevalence of normal geometry, 10.0% of non-hypertensive concentric remodeling of CCA, 9.0% of concentric and 5.0% of eccentric hypertrophy. IL-33 ≥71 pg/ml with IL-1B ≥25 pg/ml was associated with decrease of normal CCA geometry prevalence to 50.0% with increase of concentric hypertrophy rate to 41.7%; other 8.3% patients had eccentric hypertrophy of CCA. IL-33 ≥71 pg/ml ≥ IL-1B ≥20 pg/ml (p=0.05 vs control group) had 57.9% of normal geometry, 15.8% of concentric remodeling, 15.8% of concentric hypertrophy and 10.5% of eccentric hypertrophy of CCA.

Conclusion: IL-33 and IL-1B serum levels were elevated in hypertensive patients independently of presence of obesity. A pronounced isolated increase in IL-33 level was associated with abrupt increase of CCA hypertrophy prevalence, especially its concentric variant. Accompanying increase in IL-1B level reduced this effect.

Abdominal aortic aneurysms repair by entirely percutaneous endovascular approach using closure suture-based device. Prospective study of safety, feasibility and efficiency
Redouane Saady (1), Antoine Sauguet (2), Denis Doyen (1), Jean Fajadet (2)
(1) CHU Nice, Cardiologie, Nice, France – (2) Clinique Pasteur, Cardiologie, Toulouse, France

Background: Endovascular repair of abdominal aortic aneurysms (AAA) is a well documented option. This approach is usually performed by surgical cut down of the common femoral arteries (CFA). Total percutaneous access for endovascular aortic aneurysm repair (= precise technique =) has been reported. However high bleeding risk obese patients are still considered as bad candidates for this method.

Aims: We describe our experience of the entirely percutaneous vascular approach using the Prostar XL system, in our obese population in particular.

Methods: We analyzed 164 consecutive patients treated for AAA by endovascular percutaneous route between January 2007 and February 2012. Mean age of our patients was 76 years old. 25.8% of our population were women (mean body mass index = 36). All patients were treated with a bifurcated endoprosthesis. The diameter of the introducer was 18-French (F) for the main femoral access and 12F for the contralateral access. The success rate of the procedure has been described elsewhere. A total of non-surgical 328 femoral access sites were closed with the Prostar XL system.

Results: The success rate of the entirely percutaneous vascular approach procedure was 94.5% and reached 100% in obese population, with a mean delay to hospital discharge of 6 days. Nine procedure failures were deployed. All procedure failures occurred on the 18F side while the success rate was 100% with 12F introducers (p=0.002). Re-hospitalization rate due to vascular access complication (haematoma, false aneurysm, femoral access) was 2.4% after a mean follow-up of 23 months, but no difference between obese and non-obese patients was found.

Conclusion: Our results indicate that even in obese patients, usually considered as relatively contra-indicated to this strategy, the entirely percutaneous approach using the Prostar device for endovascular treatment of infrarenal AAA is safe.

Analysis of blood pressure variability in the systolic hypertension with telemonitoring: feasibility and results on 108 patients
Patrick Dary
Cabinet de Cardiologie, Saint Yrieix La Perche, France

Purpose: Blood pressure (BP) and its variability (BPV) are associated with an increased risk for cardiovascular mortality. This observational study explores the benefits of patients telemonitoring using self-measured BP to optimize treatment and its usefulness in the variability analysis

Methods: Patients with uncontrolled hypertension were enrolled during an appointment. ≥2 SBP were taken in the morning, at midday and in the evening at set times, the results being sent to a secure server. After 5 days treatment was started if the mean reading was more than 140/90. Variability analysis has been realized during all the follow up. The evaluation made at the end of the first 5 days to obtain the mean, standard Deviation (SD), coefficient of variation (CV), hight and low BP

Results: 63 women and 45 men. BP = 176/96 at inclusion dropping to 160/88 after 5 days under the same treatment. Therapeutic adjustments achieved over 12.7 days with significant decrease in BP to 143/82: −17 systolic and −6 diastolic (p<0.0001)

The success rate of variability are SD=16.63±5 and CV=0.105±0.03. There is no difference according age (<70 years CV 0.104±0.07 years CV 0.100, p=0.582) or the level of BP (BP< 160 mmhg CV 0.109/ BP> 160mmhg CV 0.100; p =0.100). At first variability is of 0.105 (32 measures, 4.7 days) with a not significant increase at the end: 0.112 (52 measures, p=0.098)

When variability >0.10, the risk of low BP increases (104/118, p<0.0001; CV =0.136/0.087, p<0.0001), for the same mean BP(146/142, p=0.152), number of treatment (2.7/2.86, p=0.443) and for the same age (69/86/88, p=0.152) SBP of all measures is lowest at midday: 164 mmhg morning, 153 mmhg midday (−11mm, p<0.0001), 163mmhg evening with the same difference at the end of follow up (147/138). The gap increases >74 years (~14mm de hg; 170/156)

Conclusions: Awareness of the variance between average clinic and average telemonitoring BP may influence the diagnostic and management of hypertension.Telemonitoring of BP allows the real time measure of the mean, SD, CV and hight and low BP after modification or new treatment.The real time analysis allows the control of hypertension to improve (figure next page).

Kharkiv National Medical University, Internal Medicine, Kharkiv, Ukraine

The aim our study was to investigate cardiometabolic risk factors and plasma interleukin-18 (IL-18) levels in relationships with hyperglycemic waist phenotype (HTGW) depend on gender of patients with arterial hypertension (AH).

Methods: Anthropometric parameters, carbohydrate and lipid metabolism, circulating IL-18 levels in 101 patients with AH (men (n=45; 44.6%) and women (n=56; 55.4 %) aged 32-80 years) were examined. HTGW was defined

© Elsevier Masson SAS. All rights reserved.
as a waist circumference (WC) of 90cm and more in male, and 85cm and more in female, and a triglyceride level of 1.7 mmol/L or more. Patients were categorized into 3 phenotype groups: 1st with hypertriglyceridemia and normal WC, 2nd with normal triglyceride level and increased WC, 3rd with HTGW.

**Results:** The patients of 3rd group characterized by maximum blood pressure levels. Body mass index (BMI) in 3rd group was also highest (31.05±1.61kg/m²) vs 1st (23.95±0.91kg/m²) and 2nd one (30.21±1.00kg/m²). Fasting insulin levels were elevated in patients of 3rd group with HTGW (14.66±0.95 mkU/ml), and same in 1st (12.52±2.79 mkU/ml) and 2nd (12.31±1.41 mkU/ml) groups.

IL-18 – pro-inflammatory cytokine levels in 3rd group were 176.97±2.38pg/ml, that was statistically higher in comparison with 1st (167.73±7.21pg/ml), and 2nd group (172.40±5.61 pg/ml; p<0.05). Plasma IL-18 in 2nd group was higher in men (172.40±5.61 pg/mg) vs women (169.53±7.04 pg/ml; p<0.05); whereas in 1st group women characterized by significantly higher IL-18 content (169.00±1.11 pg/ml) compared with men (160.83±9.35 pg/ml; p<0.05). The same tendency was found in group 3 with HTGW phenotype presence where IL-18 content in women (180.62±2.93 pg/ml) exceed cytokine level in men (167.76±3.52 pg/ml; p<0.05).

**Conclusions:** Our results can suggest that HTGW phenotype is associated with more significant in women elevation of pro-inflammatory activity, high glucometabolic risk and atherogenic metabolic risk profile and can be used as a simple and inexpensive marker to help identify patients with high cardiometabolic risk.

Pulmonary embolism in Behçet’s disease: a series of 10 patients

Tounsi Ahmed (1), Abid Leila (1), Abid Dorra (1), Triki Feten (1), Elaoud Sahar (2), Frika Feten (2), Bentati Mourad (1), Bahloul Zouhir (2), Kamoun Samir (1)

(1) CHU Hédi Chaker, Cardiologie, Sfax, Tunisie – (2) CHU Hédi Chaker, Médecine interne, Sfax, Tunisie

**Background and objective:** Pulmonary embolism is an unusual complication of Behçet's disease (BD). Our aim study is to analyse epidemiological, physiopathological and evolutive aspects of this condition.
