In Brief
Ronca et al. show that overexpression of long-pentraxin 3 (PTX3) in mice inhibits the growth of FGF-dependent tumor models. On the basis of pharmacophore modeling of PTX3-FGF2 interaction, they identify a small molecule that acts as an extracellular FGF trap and inhibits FGF-dependent tumor growth in mice.

SUMMARY

The fibroblast growth factor (FGF)/FGF receptor (FGFR) system plays a crucial role in cancer by affecting tumor growth, angiogenesis, drug resistance, and escape from anti-angiogenic anti-vascular endothelial growth factor therapy. The soluble pattern recognition receptor long-pentraxin 3 (PTX3) acts as a multi-FGF antagonist. Here we demonstrate that human PTX3 overexpression in transgenic mice driven by the Tie2 promoter inhibits tumor growth, angiogenesis, and metastasis in heterotopic, orthotopic, and autochthonous FGF-dependent tumor models. Using pharmacophore modeling of the interaction of a minimal PTX3-derived FGF-binding pentapeptide with FGF2, we identified a small-molecule chemical (NSC12) that acts as an extracellular FGF trap with significant implications in cancer therapy.

INTRODUCTION

Fibroblast growth factors (FGFs) are heparin-binding polypeptides produced by stromal and parenchymal tumor cells and are readily sequestered into the extracellular matrix by heparan sulfate proteoglycans (HPSGs). FGFs bind tyrosine kinase (TK) FGFR receptors (FGFR1–FGFR4), leading to the formation of signaling HSPG/FGF/FGFR ternary complexes (Beenken and Mohammadi, 2009). Activation of the FGF/FGFR system by overexpression, oncogenic mutations, or gene amplifications is implicated in key steps of tumor growth and progression (Beenken and Mohammadi, 2009). Moreover, compensatory upregulation of the FGF/FGFR system may facilitate the escape from angiostatic anti-vascular endothelial growth factor (VEGF) blockade (Casanovas et al., 2005; Lieu et al., 2011). Thus, experimental and clinical evidence provides a compelling biologic rationale for the development of anti-FGF/FGFR targeting agents in cancer therapy.

Thus far two major classes of FGFR inhibitors have been developed: small-molecule intracellular TK inhibitors and extracellular anti-FGFR antibodies or peptides (Ho et al., 2014). However, FGFR redundancy, limited selectivity, and significant toxicity of TK inhibitors and proteinaceous origin of extracellular FGFR antagonists may represent significant challenges for the development of effective anti-cancer drugs. An alternative or complementary approach may derive from the observation that...
FGFs are highly expressed in certain human tumors and exert paracrine and autocrine functions on cancer epithelial and stromal cells (Brooks et al., 2012), thus providing druggable targets for the development of “two-compartment” anti-FGF agents (Deci et al., 2013), as hypothesized for soluble “decoy” FGFRs (Harding et al., 2013; Ho et al., 2014), heparin derivatives, and polysulphated or polysulphonated compounds (Presta et al., 2005). However, the possibility of developing small organic molecules as extracellular multi-FGF ligand traps remains underexplored.

The soluble pattern recognition receptor long pentraxin-3 (PTX3) is produced by endothelial and immune cells in response to inflammatory signals (Garlanda et al., 2005). PTX3 binds various FGFs via its N-terminal extension, including FGF2, FGF6, FGF8b, FGF10, and FGF17, and inhibits FGF-dependent angiogenic responses (Camozzi et al., 2006; Leali et al., 2011; Presta et al., 2007; Ronca et al., 2013a). Accordingly, the acetylated pentapeptide Ac-ARPCA-NH2 (in single-letter code, hereafter referred to as ARPCA), corresponding to the N-terminal amino acid sequence PTX3(100–104), acts as a minimal anti-angiogenic FGF-binding peptide able to interfere with FGF/FGFR interaction (Leali et al., 2010). Thus, PTX3 represents a natural multi-FGF trap with potential implications for tumor therapy. Indeed, PTX3-overexpressing FGF-dependent tumor cells show a reduced angiogenic and tumorigenic potential (Leali et al., 2011; Ronca et al., 2013a, 2013b).

Here, the effect of endothelial human PTX3 (hPTX3) overexpression on FGF-dependent tumor progression was evaluated in transgenic mice, and pharmacophore modeling was used to identify a PTX3-derived small molecule acting as a FGF trap in cancer therapy.

RESULTS

Generation of Transgenic hPTX3-Expressing TgN(Tie2-hPTX3) Mice

To mimic the effect of a local and systemic delivery of hPTX3 on tumor growth, we generated transgenic TgN(Tie2-hPTX3) mice expressing hPTX3 under the control of the endothelial-specific Tie2/Tek transcription regulatory sequences. hPTX3 is expressed in various organs of these mice where it accumulates in the perivascular and stromal microenvironment (Figures 1A and 1B), leading to a significant increase of hPTX3 serum levels (105 ± 20 ng/ml versus < 1.8 ng/ml in transgenic and wild-type animals, respectively).

As anticipated, lung endothelial cells isolated from TgN(Tie2-hPTX3) animals showed impaired FGRF1 activation following stimulation by FGF2 when compared to wild-type cells (Figure 1C). In addition, aorta rings harvested from TgN(Tie2-hPTX3) mice and embedded in fibrin gel in the presence of FGF2 showed a reduced capacity to form endothelial cell sprouts but retained a full response to VEGF-A (Figure 1D). Finally, the angiogenic activity of FGF2 was significantly reduced in a subcutaneous (s.c.) Matrigel plug assay performed in TgN(Tie2-hPTX3) animals (Figure 1E). Notably, constitutive hPTX3 expression does not result in apparent defects in embryonic and post-natal development and in body weight gain; adult animals are fertile with no histological alterations of all tissues examined, including heart, liver, lungs, and kidney (data not shown). Moreover, no significant changes in the expression levels of PTX3-targeted FGFs, including Fgf2, Fgf6, Fgf8, Fgf10, and Fgf17 (Ronca et al., 2013a), was observed in different organs of TgN(Tie2-hPTX3) mice when compared to wild-type animals (Figure S1).

Tie2 Promoter-Driven Expression of hPTX3 Impairs Heterotopic Tumor Growth and Neovascularization

Transgenic adenocarcinoma of the mouse prostate (TRAMP)-C2 cells are a prototypic prostate carcinoma model driven by autocrine, androgen-upregulated FGF2 and FGF8b (Ronca et al., 2013a). To assess the impact of hPTX3 overexpression on the early phases of FGF-dependent tumor growth, we performed a short-term experiment in which TRAMP-C2 cells embedded in alginate plugs were injected s.c. in male TgN(Tie2-hPTX3) mice. After 2 weeks, alginate pellets grafted in transgenic animals showed a significant reduction of FGFR1 phosphorylation when compared to plugs implanted in wild-type animals, providing experimental evidence of the capacity of transgenic hPTX3 overexpression to disrupt ligand-dependent FGFR activation in vivo (Figures 2A and 2B). Accordingly, tumor cell proliferation rate and vascularization were drastically impaired in TRAMP-C2 plugs grafted in TgN(Tie2-hPTX3) mice (Figure 2C) with a significant inhibition of TRAMP-C2 tumor growth in a long-term s.c. assay (Figure 2D).

A significant reduction of tumor growth was observed in TgN(Tie2-hPTX3) mice also after s.c. injection of FGF-dependent B16-F10 melanoma cells or Lewis lung carcinoma (LLC) cells, a model in which the FGF/FGFR axis is associated with tumor growth and resistance to anti-VEGF therapy (Figure 2D) (Shojaei et al., 2009). Notably, no difference in the rate of tumor growth occurred in TgN(Tie2-hPTX3) animals grafted with FGF-independent TC-1 or C3 cancer cells (Figure S2A) (Accardi et al., 2014). Similarly, hPTX3 overexpression did not affect the growth of FGFR1-TRAMP-C2 lesions transduced with a constitutively activated form of the intracellular FGFR1 TK domain (Hart et al., 2000) and characterized by a faster rate of growth when compared to parental TRAMP-C2 tumors (Figure S2B).

hPTX3 overexpression inhibited the growth, proliferation rate, and vascularization of experimental liver metastases after intravenous (i.v.) injection of M5076 reticulum cell sarcoma cells (Figures 2E and 2F) (Talmadge and Hart, 1984). A similar inhibition was observed for the growth of B16-F10 melanoma lung metastases (Figures 2G and 2H) that occurred in the absence of any effect of hPTX3 expression on B16-F10 cell homing to the lungs (Figure S2C). In contrast, no difference in lung colonization was observed between wild-type and TgN(Tie2-hPTX3) animals following i.v. injection of FGF-independent TC-1 cells (Figure S2D). Together, these data support the notion that the anti-tumor effect of hPTX3 is related to its extracellular inhibitory action on the autocrine and paracrine loops of stimulation triggered by the FGF/FGFR system in FGF-dependent tumors.

Tie2-expressing monocytes (TEMs), a bone marrow (BM)-derived cell population homing the tumor microenvironment, may act as cell shuttles for a tumor-targeted delivery of anticancer therapeutics (De Palma et al., 2007). On this basis, we generated chimeric mice by myelodepletion of wild-type animals followed by reconstitution with the BM harvested from TgN(Tie2-hPTX3) or control GFP-expressing transgenic
TgN(Tie2-GFP) mice (Figures S2E and S2F). As shown in Figure 2I, myeloid-cell-mediated delivery of hPTX3 by TEMs infiltrating the s.c. TRAMP-C2 tumors (Figure S2G) caused a significant delay of tumor growth in chimeric TgN(Tie2-hPTX3) BM-transplanted mice when compared with tumors grafted in TgN(Tie2-GFP) BM-transplanted animals. The inhibitory effect was paralleled by a significant reduction of tumor cell proliferation, but not of tumor vascularization (Figures S2H and S2I), possibly as a consequence of the lower local and systemic concentration of hPTX3 produced by transplanted myeloid cells compared to hPTX3 transgenic animals.

**Tie2 Promoter-Driven hPTX3 Production Impairs Orthotopic and Autochthonous Multistage Tumor Growth**

Next, we evaluated the effect of stroma-derived hPTX3 on the growth of syngeneic murine pancreatic and mammary carcinoma cells orthotopically grafted in TgN(Tie2-hPTX3) mice.

Figure 1. Transgenic TgN(Tie2-hPTX3) Mice

(A) RT-PCR and western blot analyses of the expression of transgenic hPTX3 in wild-type (WT) and TgN(Tie2-hPTX3) mice. (B) Immunostaining of CD31 (blood vessels) and hPTX3 protein. (C) Immunostaining for pFGFR1 and CD31 of FGF2-stimulated endothelial cells isolated from WT and TgN(Tie2-hPTX3) lungs. Intensity of pFGFR1 signal was quantified and normalized to DAPI area. The boxes extend from the 25th to the 75th percentiles, lines indicate the median values, and whiskers indicate the range of values. Inset: RT-PCR analysis on isolated cells. (D) Quantification of the number of sprouts at day 6 and representative images of fibrin-embedded aorta rings from WT and TgN(Tie2-hPTX3) mice treated with FGF2 or VEGF-A. (E) qRT-PCR (n = 8 mice/group) and immunofluorescence analyses of CD31 expression in vehicle and FGF2 Matrigel plugs. Scale bars, 50 μm (B and E), 30 μm (C), and 400 μm (D). Data are mean ± SEM. *p < 0.05, and #p < 0.001. See also Figure S1.
When compared to wild-type animals, intra-pancreatic injection of Panc02 tumor cells in TgN(Tie2-hPTX3) mice resulted in a significant reduction of tumor burden and enhancement of animal survival (Figure 3A). Similarly, a significant delay in the appearance of mammary tumor nodules, decreased tumor growth, and increased survival time were observed in female TgN(Tie2-hPTX3) mice with respect to control animals after transplantation of syngeneic EO771 breast carcinoma cells into the mammary fat pad (Figure 3B).

TRAMP mice represent an autochthonous multistage model of prostate cancer in which the FGF/FGFR system plays a relevant role (Polnaszek et al., 2003). To further assess the anti-neoplastic potential of the FGF trap activity of hPTX3, the prostatic tumor progression in double-transgenic TgN(Tie2-hPTX3)/TRAMP mice was compared to the progression in age-matched TRAMP animals at 10 and 12 weeks of age. Quantitative histological analysis revealed a lower incidence of well-differentiated and moderately differentiated tumors (Figure 3C) and a reduction of Ki67+ tumor cells (Figure 3D) in TgN(Tie2-hPTX3)/TRAMP mice, index of significant delay of prostatic tumor progression in hPTX3-expressing mice. This effect was transient and was not observed at later stages of tumor progression in which poorly differentiated or neuroendocrine tumors arose (data not shown), possibly due to compensatory mechanisms that overcome FGF inhibition by PTX3. Even though further experiments will be required to assess the mechanisms able to overcome PTX3-mediated oncosuppressive effects, the data clearly show that PTX3 can delay, at least transiently, the progression of prostate cancer in the TRAMP model.

**Homozygous Ptx3 Inactivation Enhances FGF-Dependent Angiogenesis, Tumor Growth, and Metastasis**

Ptx3−/− mice develop normally and do not show any gross abnormality, even though Ptx3−/− females are subfertile. Ptx3 deficiency causes a reduced immune response to pathogens and increases tissue damage in ischemic myocardium and atherosclerotic lesions (see Daigo et al. [2014] for a more detailed description of the Ptx3−/− mouse phenotype). Also, recent observations have shown that the growth of cardiac carcinoma-induced skin tumors is delayed in these animals (Bonavita et al., 2015). To further evaluate the impact of PTX3 on tumor growth, we compared the angiogenic activity of FGF2 protein and the tumorigenic and metastatic activity of melanoma B16-F10 cells when assessed in syngeneic Ptx3−/− mice versus wild-type and TgN(Tie2-hPTX3) animals. As shown in Figure 3E, Ptx3 knockout results in a significant increase of both basal and FGF2-triggered angiogenic responses in the Matrigel plug assay when compared to those observed in TgN(Tie2-hPTX3) and wild-type animals. It must be pointed out that the s.c. injection of Matrigel induces per se a mild pro-inflammatory reaction, leading to the co-expression within the plug of PTX3 and FGF2, thus explaining the effect of Ptx3 knockout on the basal neovascular response in this assay (Leali et al., 2012). In agreement with these observations, the tumorigenic and metastatic activities of B16-F10 cells were significantly enhanced in Ptx3 null animals in respect to wild-type and hPTX3-overexpressing mice (Figures 3F and 3G). Thus, PTX3 appears to act as a natural brake of FGF-mediated angiogenesis, tumor growth, and metastasis. This inhibitory activity is further enhanced by Tie2 promoter-driven hPTX3 overexpression in tumor-bearing mice. These observations paved the way for the exploitation of the FGF trap activity of PTX3 in cancer therapy and for the development of PTX3-derived anti-FGF synthetic compounds.

**Identification of a PTX3-Derived Small-Molecule FGF Trap**

PTX3 is a 340-kDa protein composed of eight protomers of 381 amino acids each (Inforzato et al., 2010). The complex proteinaceous structure of PTX3 hampers its pharmacological exploitation. In this context, we identified the acetylated pentapeptide PTX3(100–104) ARPCA as the minimal amino acid sequence able to bind FGF2 and interfere with FGF2/PTX3 and HSPG/FGF2/FGFR1 interactions (Leali et al., 2010). ARPCA acts as a potent FGF2 and FGF8b antagonist (Leali et al., 2010; Ronca et al., 2013a; Giacomini et al., 2015), representing a useful starting point for the rational identification of low-molecular-weight, nonpeptidic FGF antagonists.

On this basis, an atomistic model of the ARPCA/FGF2 complex was generated to identify the physico-chemical determinants required for productive ARPCA/FGF2 interaction. This information was translated into a pharmacophore model for the identification of drug-like hits via the screening of small-molecule libraries (Colombo et al., 2010). First, the principal conformations populated by ARPCA in solution, derived from a 200-ns-long explicit water molecular dynamics (MD) simulation, were subjected to multiple docking runs on the FGF2 surface, followed by MD refinement of the resulting complex (~100 ns). The results (detailed in the Supplemental Information) showed that ARPCA engages the FGF2 surface that faces the D2-D3 linker and D3 domain of FGFR (Plotnikov et al., 1999). The analysis of the statistical distribution of ARPCA/FGF2 interactions was consistent

---

(B) Western blot analysis and pFGFR1/FGFR quantification normalized to β-actin.

(C) PTX3, CD31, and Ki67 immunostaining, CD31+ and Ki67+ quantification normalized to DAPI area, and relative levels of CD31 and cyclin D1 mRNA expression normalized to 18S rRNA. Eight to ten mice/group in (A)–(C).

(D) Growth of s.c. TRAMP-C2, LLC, and B16-F10 tumors in WT and TgN(Tie2-hPTX3) mice (n = 10–12 mice/group).

(E–H) M5076 (E and F) and B16-F10 (G and H) cells were injected i.v. in WT and TgN(Tie2-hPTX3) mice (n = 10 mice/group). After 3 weeks, liver (E) and lungs (G) were stained for Ki67.

(I) Growth of s.c. TRAMP-C2 tumors in WT chimeric mice reconstituted with TgN(Tie2-hPTX3) or control TgN(Tie2-GFP) bone marrow (BM); n = 10 mice/group. Scale bars, 30 μm (A), 100 μm (F [CD31/PTX3 and Ki67], H [Ki67]), 200 μm (H [CD31/PTX3]), and 400 μm (F and H [H&E]). Data are mean ± SEM. In box and whiskers graphs, boxes extend from the 25th to the 75th percentiles, lines indicate the median values, and whiskers indicate the range of values. *p < 0.05, **p < 0.01, and ***p < 0.001. See also Figure S2.
with previously published nuclear magnetic resonance (NMR) saturation-transfer difference (STD) data, indicating that the peptide contacts FGF2 via the methyl groups of Ala1 and Ala5 and of the acetyl capping group (Leali et al., 2010). Next, the ARPCA key functional groups, combined with the characterization of their relative space orientations, were used to build a pharmaco-phore model for the screening of the NCI2003 small-molecule database containing \( C_{24} \) compounds (Developmental Therapeutics Program NCI/NIH at https://dtp.cancer.gov/).

Filtering of the resulting set according to the Lipinsky drug-likeness rules returned 25 compounds. Ten of them, made available from the National Cancer Institute (NCI), were subjected to a preliminary screening for their capacity to prevent the formation of HSPG/FGF2/FGFR1(IIIc) ternary complexes in a FGF2-mediated cell-cell adhesion assay. This assay is based on the capacity of FGFs to interact simultaneously in trans with HSPGs and FGFRs expressed on neighboring cells, thus causing FGF-mediated cell-cell adhesion (Richard et al., 1995); FGF antagonists hamper FGF-mediated intercellular adhesion by binding FGF and preventing its interaction with HSPGs or FGFRs (Leali et al., 2010). As shown in Figure S3 A, the 480-Da compound 4,4,4-trifluoro-1-(3-hydroxy-10,13-dimethyl-2,3,4,7,8,9,11,12,14,15,16,17-dodecahydro-1H-cyclopenta[a]phenanthren-17-yl)-3-(trifluoromethyl)butane-1,3-diol (NSC172285, herewith named NSC12; Figure 4A) prevented the formation of the HSPG/FGF2/FGFR1 complex (half maximal inhibitory concentration (IC\(_{50}\) \( C_{24} \) \( 10 \) \( M; Figure 4B), whereas the other compounds were devoid of significant activity. On this basis, NSC12 was characterized further, and the NSC21 compound was used as a negative control.

In a first set of experiments, NSC12 was investigated by surface plasmon resonance (SPR) analysis for its capacity to prevent the binding of FGF2 to heparin immobilized to a BIAcore sensor chip or to an immobilized sFGFR1(IIIc)/Fc chimera. As shown in Figure 4C, NSC12 prevented the formation of the HSPG/FGF2/FGFR1 complex (half maximal inhibitory concentration (IC\(_{50}\) \( C_{24} \) \( 10 \) \( M), whereas the other compounds were devoid of significant activity. On this basis, NSC12 was characterized further, and the NSC21 compound was used as a negative control.
immobilized receptor (ID$_{50}$ ~30 μM). No effect was exerted by NSC21 on either sensor chip. Thus, as observed for PTX3/FGF2 and ARPCA/FGF2 complexes (Leali et al., 2010), NSC12 interferes with FGF2/FGFR1 interaction without affecting the ability of the growth factor to interact with heparin or HSPGs.

The capacity of NSC12 to bind to immobilized FGF2 was confirmed by SPR spectroscopy. The SPR binding isotherm (Figure 4D) shows a Langmuir-like shape for monovalent binding with a dissociation constant (K$_d$) equal to 51 ± 7 μM. The 1:1 stoichiometry of the FGF2:NSC12 interaction was confirmed also by surface density SPR measurements (Maiolo et al., 2012) performed at 100 μM NSC12 and showing that 1.28 x 10$^{10}$ molecules/mm$^2$ of NSC12 bind to 1.45 x 10$^{10}$ molecules/mm$^2$ of immobilized FGF2.

FGF2/NSC12 interaction was investigated also by the contact angle molecular recognition (CONAMORE) biosensor that probes the nanomechanical aspects of binding, complementing the information obtained by SPR (Maiolo et al., 2012). The CONAMORE binding isotherm performed on the same FGF2 chip used for SPR (Figure 4D) evidences that the onset of significant nanomechanical effects of FGF2 binding occurs at ~40 μM NSC12, consistent with the K$_d$ calculated by SPR. In addition, no nanomechanical effect is registered when NSC12 is run onto a urea-denatured FGF2 chip (Figure 4D), further pointing to the specificity of the interaction.

Docking and MD simulations performed on the NSC12/FGF2 system indicated that NSC12 and ARPCA, while sharing the same pharmacophoric points necessary to anchor FGF2, do not target entirely identical or overlapping regions on the FGF2 molecule, as expected given their different chemical nature and pharmacophore design. Indeed, besides engaging the FGF2 surface that faces the D2-D3 linker and D3 domain of FGFR, NSC12 further extends into the FGF2 region facing the FGFR D2 domain (D2), as detailed in the Supplemental Information and in Figure 4E. On this basis and given that the D3 domain
does not adopt a stable persistent three-dimensional fold in solution (Herbert et al., 2013), the D2 domain was used as a probe to investigate the overall effects of NSC12 on the FGF2/FGFR complex by NMR. Relaxation data demonstrate that NSC12 shifts the FGF2/D2 equilibrium toward the uncomplexed forms, as deduced from the decrease of the average $^{15}$N transverse relaxation rate value measured for D2 and FGF2 upon NSC12 addition to the D2/FGF2 complex (Supplemental Information and Figure S3B).

Finally, when tested by SPR analysis on all canonical FGFs (Itoh and Ornitz, 2004), NSC12 also binds immobilized FGF3, FGF4, FGF6, FGF8, FGF16, FGF18, FGF20, and FGF22 with $K_d$ values ranging between ~16 and ~120 $\mu$M (Figure 4F). No apparent interaction was observed for the other FGFs tested, possibly because of the limited sensitivity of the method due to the low molecular weight of NSC12 or to the low efficiency of the immobilization procedure for some of the FGFs tested.

On this basis, the capacity of NSC12 to affect the activity of the immobilization procedure for some of the FGFs tested. In keeping with its capacity to antagonize FGF2/FGFR1 interaction and tumor cell proliferation, as well as on tumor cell proliferation and neovascularization in FGF-dependent tumors.

To define a therapeutically effective dose and to assess the FGF antagonist activity of NSC12 in vivo, TRAMP-C2 cells were embedded in alginate plugs and grafted s.c. in syngeneic male mice that were treated intraperitoneally (i.p.) every other day for 1 week with increasing doses of NSC12 (from 2.5 to 10 mg/kg). NSC12 caused a significant decrease of tumor weight, tumor cell FGFR1 phosphorylation and proliferation, and tumor CD31+ neovascularization with a consequent increase of tumor cell death (as assessed by TUNEL staining). Notably, in keeping with in vitro observations, i.p. administration of NSC12 did not exert any effect in vivo on FGF-independent HCC827 tumor cells, causing only a limited inhibition of the scarce neovascular response elicited by these cells (Figure 6G). Again, NSC21 was ineffective in all the alginate plugs tested.

Together, these data provide strong experimental evidence about the capacity of a small-molecule FGF trap to disrupt FGF/FGFR signaling in vivo, leading to inhibition of tumor cell proliferation and neovascularization in FGF-dependent tumors.
Figure 5. In Vitro Anti-tumor Effects of NSC12

(A and B) FGFR1 and pFGFR1 immunostaining (A), viable cell counting, and cell cycle analysis (B) of HUVE cells treated with FGF2, VEGF-A, or FBS in the presence of NSC12 or NSC21.

(C) HUVE cell spheroids were stimulated with FGF2 or VEGF-A in the absence or presence of 1.0 μM NSC12 or NSC21. After 24 hr, the number of sprouts or spheroids were counted.

(D) FGF2 and VEGF-A alginate pellets were placed on top of the chick embryo CAM at day 11 in the absence or presence of NSC12 or NSC21. At day 14 blood vessels around the sponges were counted (n = 8 eggs/group).

(E and F) Viable cell counting and cell cycle analysis of prostate cancer cells (E) and lung cancer cells (F).

*p < 0.05, and #p < 0.001. Scale bars, 20 μm (A) and 100 μm (C). Data are mean ± SEM. For cell cycle analyses: p < 0.01, *S phase, /G0/G1 phase, and /G2/M phase. See also Figure S4.
Figure 6. NSC12 Inhibits the FGF/FGFR System in FGF-Dependent Tumors

(A–D) Male mice were implanted s.c. with TRAMP-C2/alginate plugs and treated i.p. every other day with NSC12, NSC21, or vehicle (n = 4–6 mice/group). After 1 week, harvested plugs were weighed (A), processed for immunofluorescence analysis of FGFR1 and pFGFR1 (B) or of CD31 and Ki67 (C) or for pFGFR1/FGFR1 quantification by western blot analysis of FGFR1 and pFGFR1 (data are normalized to β-actin; D).

(legend continued on next page)
Inhibition of Tumor Growth by Parenteral and Oral Delivery of NSC12

On the basis of results described above, NSC12 was assessed for its capacity to inhibit the tumorigenic activity of FGF-dependent TRAMP-C2 cells and of human prostate DU145 and lung H520 tumor cells following i.p. administration in syngeneic and nude mice, respectively. To this purpose, tumor cells were injected s.c., and animals were randomly distributed in vehicle-, NSC12-, or NSC21-treated groups when tumors were palpable. As shown in Figure 7A, NSC12 exerted a significant inhibitory effect on the growth of both murine and human tumor grafts, whereas NSC21 was ineffective. Moreover, NSC12 inhibited the formation of experimental lung metastases after i.v. injection of B16-F10-luc cells (Figure 7B) and of spontaneous lung metastases induced by orthotopic grafting of breast carcinoma EO771 cells into the mammary fat pad followed by surgical removal of the primary tumor (Figure 7C). In contrast, NSC12 did not affect the growth of FGF-independent TC-1 and C3 tumor grafts or of TRAMP-C2 and LLC lesions overexpressing the constitutively activated form of the intracellular FGFR1 TK domain, thus confirming the specificity of the effect (Figure 5D).

Finally, to establish whether NSC12 may also exert a significant anti-tumor activity after oral administration, male mice were injected s.c. with TRAMP-C2 cells embedded in alginate plugs and treated by gavage with 7.5 mg/kg NSC12 or NSC21 for 4 days. Strikingly, gavage administration of NSC12 significantly impaired FGFR1 phosphorylation in TRAMP-C2 plugs when compared to plugs from animals treated with NSC21 or vehicle (Figure 7D). To confirm the oral activity of NSC12 also in human tumors, FGF-dependent H520 cells were grafted s.c. in nude mice. When tumors were palpable, animals were randomly distributed in three experimental groups and treated orally with 7.5 mg/kg NSC12 or NSC21 or vehicle. As shown in Figure 7E, gavage administration of NSC12 resulted in a significant inhibition of H520 tumor growth that was confirmed by measuring the end-stage tumor weight. This occurred in the absence of any effect of drug administration on body weight and survival of treated animals.

**DISCUSSION**

Here we demonstrate that Tie2 promoter-driven hPTX3 overexpression in transgenic mice inhibits tumor growth, angiogenesis, and metastasis in heterotopic, orthotopic, and autochthonous FGF-dependent tumor models. On this basis, pharmacophore modeling of the interaction of the minimal PTX3-derived FGF-binding pentapeptide ARPCA with FGF2 was used for the identification of NSC12 as a small-molecule FGF trap active by parenteral as well as by gavage administration in tumor-bearing mice.

Several pieces of evidence support the hypothesis that the oncosuppressive effects of hPTX3 are due to its capacity to act as a natural FGF trap: (1) the endothelium of TgN(Tie2-hPTX3) mice shows a reduced response to FGF2 in various angiogenesis assays but retains a full capacity to respond to VEGF stimulation; (2) inhibition of FGFR1 phosphorylation occurs in FGF-dependent TRAMP-C2 cells grafted in TgN(Tie2-hPTX3) mice; and (3) hPTX3 expression does not affect the growth of FGF-independent TC-1 or C3 tumors. We cannot rule out the possibility that PTX3 may have multiple impacts on tumor growth (Bonavita et al., 2015). Nevertheless, our data support the notion that the anti-tumor effects of hPTX3 are related to its inhibitory action on the autocrine and paracrine loops of stimulation triggered by the FGF/FGFR system in FGF-dependent tumors, setting the basis for the identification of a PTX3-derived small-molecule FGF trap. Clearly different from FGFR blockers, PTX3 and PTX3-derived FGF traps are anticipated to be ineffective on tumors driven by ligand-independent FGFR activation, as shown for FGFR1-TRAMP-C2 cells grafted in TgN(Tie2-hPTX3) mice.

ARPCA, corresponding to the amino acid sequence PTX3 (100–104), represents the minimal FGF2-binding peptide able to antagonize FGF2 activity by interacting with the FGFR-binding region of the growth factor. These findings provided the bases for the design of a pharmacophore model of ARPCA/FGF2 interaction that was used for in silico screening of the NCI2003 small-molecule database, thus allowing the identification of NSC12 as an ARPCA mimic. As anticipated, NSC12 binds FGF2 with a 1:1 stoichiometry and inhibits the formation of bioactive HSPG/FGF2/FGFR1 ternary complexes by inhibiting FGF2/FGFR interaction with no effect on FGF2/heparin interaction. Also, MD simulation-based studies of the FGF2/ARPCA and FGF2/NSC12 systems indicate that, because of the design process, both molecules may engage the FGF2 surface that faces the FGFR D3 domain and D2-D3 linker. Moreover, NSC12 further extends its interaction into the FGF2 region facing the FGFR D2 domain. Accordingly, NMR relaxation data showed the ability of NSC12 to cause the dissociation of the FGF2/D2 complex. Even though further experiments involving the D2-D3 FGFR domains will be required to fully elucidate the inhibitory mechanism of NSC12, the combined MD, NMR, biochemical, and biological data provide compelling evidence of the ability of the compound to act as an FGF antagonist.

Previous studies had identified the small molecule sm27 as a mimic of the FGF2-binding sequence of thrombospondin-1 able to engage the heparin-binding site of FGF2 (Pagano et al., 2012). As observed for other anionic compounds (Presta et al., 2005), sm27 may interact with the heparin-binding domain of a variety of signaling proteins with possible unsought side effects. In contrast, the action of NSC12 appears to be restricted to FGFR family members due to its direct effect on FGF/FGFR interaction with no effect on the heparin-binding VEGF-Aisoform isoform. Accordingly, NSC12 inhibits the proliferation of various FGF-dependent murine and human cancer cell lines with no inhibitory

(E–G) Mice implanted s.c. with alginate plugs containing FGF-dependent human DU145 (E) or H520 (F) cells or FGF-independent human HCC827 (G) cells were treated i.p. every other day with 7.5 mg/Kg NSC12, NSC21, or vehicle for 1 week (n = 4–6 mice/group). Harvested plugs were weighed, and immunofluorescence analysis was performed.

Scale bars, 30 μm (B), 50 μm (E, F, and G [H&E]), and 100 μm (E, F, and G [CD31, TUNEL, and Ki67]). Data are mean ± SEM. In box and whiskers graphs, boxes extend from the 25th to the 75th percentiles, lines indicate the median values, and whiskers indicate the range of values. *p < 0.01, #p < 0.001, and ^p < 0.05 versus NSC12 at 2.5 and 5 mg/Kg. See also Figure S5.
Figure 7. Anti-tumor and Anti-metastatic Activity of NSC12

(A) Growth of s.c. TRAMP-C2, DU145, and H520 tumors in mice treated i.p. (arrows) with NSC12, NSC21, or vehicle (n = 10–16 mice/group).

(B) B16-F10-luc cells were injected i.v., and mice were treated i.p. for 2 weeks every other day with NSC12, NSC21, or vehicle (n = 6–8 mice/group). Bioluminescence imaging of lung colonization at day 21 is shown as is count of lung macrometastases at day 28.

(C) Number of spontaneous lung macrometastases 5 weeks after primary EO771 tumor removal and treatment with DMSO, NSC12, or NSC21 (n = 8–10 mice/group).

(legend continued on next page)
effect on HCC827 cancer cells that harbor a tumor-driving mutation of the EGFR TK domain and on FGF-independent cancer cell lines. Thus, NSC12 may act as a selective “two-compartment” epithelial-stromal targeting agent in FGF/FGFR-dependent tumors. Accordingly, i.p. and gavage administration of NSC12 hampers FGF phosphorylation, angiogenesis, and primary and metastatic growth of FGF-dependent murine and human tumors in mice.

The FGF/FGFR system is implicated in various steps of tumor growth and progression (Beenken and Mohammadi, 2009). In addition, activation of the FGF/FGFR pathway is a mechanism of tumor escape in response to anti-VEGF therapies (Casanovas et al., 2005; Lieu et al., 2011). Thus, FGF blockade may represent a valid therapeutic option for selected tumors driven by an aberrant ligand-dependent FGFR activation (Dieci et al., 2013). However, the development of drugs specifically targeting the FGF/FGFR pathway proved to be difficult, in part due to the high redundancy and pleiotropic effects of FGF and FGFR family members. Blockade of FGFR signaling by selective or broad-spectrum TK inhibitors has been associated with toxicity (Dieci et al., 2013), and a monoclonal antibody directed against FGFR1 has failed because of severe weight loss associated with hypothalamic binding (Sun et al., 2007). On the other hand, an allosteric multi-FGFR blocker with promising therapeutic implications has been described recently (Bono et al., 2013).

Drugs targeting FGF ligands may represent an interesting alternative to FGFR inhibitors. They include monoclonal antibodies and FGFR-derived decoy molecules acting as FGF traps (Harding et al., 2013; Ho et al., 2014). These molecules, however, have various limitations due to their proteinaceous origin. Our data demonstrate that NSC12 interacts with all members of the canonical FGF subfamilies involved in the growth of different human tumors (Ronca et al., 2015). Moreover, NSC12 prevents FGF interaction with all four FGFRs. Thus, NSC12 represents a small-molecule multi-FGF trap with potential implications for cancer therapy. Of note, in keeping with the lack of pathological consequences following constitutive hPTX3 expression in transgenic mice, the anti-tumor action of NSC12 occurred in the absence of any systemic toxic effect in treated animals.

Data from phase I and II clinical trials indicate that inhibition of the FGF/FGFR system may show anti-tumor activity and provide an incentive to develop additional safer and more efficacious drugs (Dieci et al., 2013). NSC12 represents a lead compound for the development of orally active small-molecule therapeutics for the treatment of tumors in which the ligand-dependent activation of the FGFR pathway is an oncogenic driver or is involved in the escape to conventional anti-cancer/anti-angiogenic therapies. Finally, from a broader perspective, our data emphasize the possibility to exploit protein interactome for the design of orally active small-molecule multi-ligand traps with promising implications in cancer therapy.

**EXPERIMENTAL PROCEDURES**

**Reagents and Cell Cultures**

Reagents, recombinant proteins, and cell lines are described in the Supplemental Experimental Procedures.

**NSC12 Identification**

Molecular dynamics simulations of ARPCA and NSC12, generation of a structural ARPCA-FGF2 complex model, pharmacophore model generation, screening process and parameters, and NMR analysis are detailed in the Supplemental Experimental Procedures.

**Western Blotting and PCR Analyses**

Tissues and tumor lysates were separated by SDS-PAGE and immunodetected with specific antibodies as described in the Supplemental Experimental Procedures. RT-PCR and qRT-PCR were performed using equal amounts of input RNA and applying specific amplification conditions as detailed in the Supplemental Experimental Procedures.

**Surface Plasmon Resonance and CONAMORE**

SPR analyses were performed using a Biacore X-100 apparatus (Biacore). Experimental conditions for SPR and details for CONAMORE analyses are described in the Supplemental Experimental Procedures.

**Angiogenesis Assays**

In vitro endothelial cell sprouting, ex vivo murine aorta ring, and in vivo CAM and Matrigel plug assays are described in the Supplemental Experimental Procedures.

**Other Assays**

Protocols used for cell proliferation, cell-cell adhesion, immunostaining, and other in vitro assays are detailed in the Supplemental Experimental Procedures.

**Transgenic Mice**

Tg(Tie2-hPTX3) mice were generated via injection of vesicular stomatitis virus G protein (VSV-G)-pseudotyped Tie2-hPTX3 lentiviral particles into

(D) Inhibition of FGFR1 activity in s.c. TRAMPC-C2/alginate plugs after 4-day oral treatment with NSC12 (7.5 mg/Kg; 4–6 mice/group). pFGFR1/FGFR1 was quantified and normalized to DAPI area. Scale bar, 30 μm.

(E) Growth of H220 tumors in mice orally treated (arrows) with NSC12, NSC21, or vehicle. At the end of the experiment, harvested tumors were photographed and weighed (n = 10–12 mice/group).

Data are mean ± SEM. In box and whiskers graphs, boxes extend from the 25th to the 75th percentiles, lines indicate the median values, and whiskers indicate the range of values. *p < 0.05, **p < 0.01, ***p < 0.001, and ns = not significant. See also Figure S6.
C57BL/6 embryos. Tie2-hPTX3-manipulated embryos were implanted into the oviduct of pseudopregnant CD1 mice, pups were genotyped for the presence of hPTX3 and lentiviral vector backbone, and the transgenic strain was maintained as described in the Supplemental Experimental Procedures. TRAMP mice were purchased from the Jackson Laboratory. Double-transgenic TgN(Tie2-hPTX3)/TRAMP mice were generated by crossing homozygous TRAMP females with Tie2-hPTX3 males.

Animal Experiments

Subcutaneous tumor models were performed by injecting TRAMP-C2 (5 × 10^6), LLC (5 × 10^6), and B16-F10 (1 × 10^6) cells into the flank of nude mice. Tumor growth was measured by using calipers, and tumor volume (V) was calculated as follows: V = (length × width^2) / 2. For experimental metastasis assays, M5076 (3 × 10^5) and B16-F10 (1 × 10^6) cells were injected via the tail vein. Panc02 cells were used for orthotopic tumor growth, and E0771 cells were used for orthotopic and spontaneous metastasis models. Experimental conditions, tumor and metastasis assays, treatments, and all procedures are detailed in the Supplemental Experimental Procedures.

Ethical Regulations

Animal experiments were approved by our local animal ethics committee (OPBA) at the University of Brescia and were executed in accordance with national guidelines and regulations.

Statistical Analyses

Statistical analyses were performed using the statistical package Prism 5 (GraphPad Software) as detailed in the Supplemental Experimental Procedures. Differences were considered significant with p < 0.05.

SUPPLEMENTAL INFORMATION

Supplemental Information includes Supplemental Experimental Procedures and six figures and can be found with this article online at http://dx.doi.org/10.1016/j.ccell.2015.07.002.

AUTHOR CONTRIBUTIONS

R.R. conceived in vivo experiments, generated mice, and analyzed the data. A.G. conceived in vitro experiments, analyzed the data, and revised the manuscript. S.R. performed animal experiments. R.M. and G.E. provided lentiviral vectors. M.M. synthetized NSC12. E.M., and G.C. generated the pharmacophore model and performed MD simulations. A.G. performed histological analyses. K.P. conceived in vitro experiments, analyzed the data, and revised the manuscript. R.R. wrote the manuscript.

ACKNOWLEDGMENTS

This work was supported by grants from Ministero Istruzione, Università e Ricerca (FIRST project RBA11H2R9 2011), Associazione Italiana Ricerca sul Cancro (AIRC grant 14395) to M.P., and AIRC grant IG 15420 and Fondazione Cariplo (grant 2011.1800 “Premio Fondazione Cariplo per la Ricerca di Frontiera”) to G.C. A.G. and S.M. were supported by Fondazione Italiana per la Ricerca sul Cancro fellowship, E.D.S. and M.P. by a Fondazione Veronesi fellowship, and K.P. by a Fondazione Antonio De Marco grant. NSC compounds were from Drug Synthesis and Chemistry Branch, Developmental Therapeutics Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute (USA). The authors are grateful to C. Garlanda for providing Ptx3^R5/C mice; B. Bottazzi, D. Moli, M. De Palma, L. Zetta, and P. Bergese for helpful discussion and criticisms; and M. Belleri, M. Corsini, A. Bugatti, and D. Leali for technical support.
