Results: Four samples were taken to culture from inner tube and outer tube of a endoscope. Two samples did not meet the standards of high-level disinfection procedures. After the infection control team involving in investigation and analyzing these results, we improved the clean procedure and added a drying equipment in endoscopic cabinet. The incident was terminated.

Conclusions: The incident unveiled the clean and disinfection procedure should be implemented for the safety and quality of endoscopy. The concentration of detergents should be detected. We also considered the training for new staff. It should include endoscopic clean and disinfection, storage location, and space clean level maintenance.

SURVEILLANCE OF CENTRAL VENOUS CATHETER (CVC) INFECTION IN NICU IN SWACH

J. Vera-alaine, M. Masrinwati, M. Salibah, L. Maria, S. M. Fong. Infection control unit, Sabah Women and Children Hospital, (SWACH) Malaysia

Introduction: Nosocomial infections are a major problem among neonates and are responsible for significant morbidity and mortality in the NICU.

Central venous catheters are one of the more commonly used devices in NICU, usually for the purposes of total parenteral nutrition and medication. Currently, in Malaysia, we do not have any surveillance data on central venous catheter infections in the NICUs.

Objective: The objectives of this study are to determine the incidence and outcome of central venous catheter (CVC) infection in NICU with the implementation of CVC bundle.

Methods: This is a prospective cohort study. All neonates in NICU who had central venous catheter such as umbilical venous catheters and peripherally inserted central catheters inserted during the hospitalization from February 2014 to August 2014 were included in the study. All positive blood cultures occurring during this period were defined as CVC related blood stream infection.

Results: There were a total of 278 out of 1327 babies who had CVC inserted during the study period. There were a total of five positive blood cultures with an incidence of 1.79%. The incidence of blood stream infection per 1000 catheter days was 0.38. The three most common microorganisms associated with CVC were methicillin resistant coagulase negative Staphylococcus followed by Klebsiella pneumoniae and Candida Albicans. Two of the babies with CVC infections expired giving rise to a case fatality rate of 0.71%.

Conclusion: The CVC infection rate is relatively low in NICU. However, despite the low rate CVC infection, it is important to note that CVC infection may directly or indirectly contribute to the mortality and outcome of the babies. Hence it is crucial to constantly educate health-care worker on the compliance of CVC bundle and the need to monitor CVC infection through surveillance.

POINT PREVALENCE SURVEY (PPS) OF CATHETER-RELATED INFECTION RATE ANALYSIS

Yu-Hsiu Lin a,b, Yu-Hui Chen a,c, Li-Hsiang Su d, Ching-Tzu Hung e, Zhi-Yuan Shi f, aInfection Control Committee, Taiwan; bChi Mei Medical Center, Taiwan; cChi Mei Medical Center, Liouying, Taiwan; dChi Mei Medical Center, Tainan City; eKaohsiung Chang Gung Memorial Hospital, Taiwan; fKaohsiung Medical University Hospital, Taiwan; gTaichung Veterans General Hospital, Taiwan

Purpose: Use of PPS methods, analysis of four medical institutions in the ICU catheter-related infections.

Methods: The use of point prevalence survey means, the four medical institutions in ICUs HAI investigation, infection control practitioner in daily from 10:00 to ward before the completion of the investigation confirmed invasive pipeline, completed in two weeks, the patient’s medical care associated infections, etc. data collection.

Results: Of 429 surveyed patients in 4 hospitals, 8.4% had an HAI (36/429). bloodstream infection represented the most common type of HAI(3.3%), followed by Pneumonia and other lower respiratory tract infections 2.1% (9/429), urinary tract infection 1.4% (6/429), surgical site infection 0.9% (4/429). Total catheter rate was 81.4% (349/429), central venous catheter 60.8% (261/429), urine retention catheter 46.6% (200/429). Endotracheal tube 40.3% (173/429). By chi-square test using a catheter patient ratios have significantly related to the occurrence of HAI (CVC catheter P < .005, catheter P < .05, respirators P = 0.013. Central venous catheters cause of nosocomial bloodstream infection risk factors odds ratio 13.3, the patient’s urinary tract infection catheter odds ratio was 0.63, the patient’s ventilator pneumonia odds ratio of 0.04.

Conclusion: Invasive catheter-related infection is caused by healthcare risk factors. Thus the combined infection control measures are required to be removed as soon as invasive ductal to reduce healthcare-associated infections.

COLONIZATION AND CONTAMINATION OF ONE MAJOR STRAIN OF PSEUDOMONAS AERUGINOSA IDENTIFIED BY ENVIRONMENT SAMPLING OF HEMODIALYSIS UNITS

Wei-Fang Chen a, Ya-Chien Hung b, Yi-Li Shih c, Ya-Ting Yang b, Chung-Hsu Lai c,d,e, Hsi-Hsun Lin b, aDivision of Infection Control Laboratory, E-Da Hospital/I-Shou University, Kaohsiung City, Taiwan; bInfectious Diseases, E-Da Hospital/I-Shou University, Kaohsiung City, Taiwan; cGraduate Institute of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung City, Taiwan; dGraduate Institute of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung City, Taiwan; eTaichung Veterans General Hospital, Taiwan

Purpose: The aim of this study is to investigate the Pseudomonas aeruginosa isolates obtained from environment sampling of hemodialysis (HD) units.

Methods: Environment sampling included inlet and outlet of dialysis machine in HD units (zone A, B, and C) and intensive care units (ICUs), and water of reverse osmosis (RO) system. Genotype analysis of P. aeruginosa was performed by pulsed-field gel electrophoresis (PFGE).
Results: From January 2011 to March 2014, a total of 75 (2.5%) isolates of *P. aeruginosa* were obtained from 3059 samples. Thirty-one isolates were in zone A, 25 in zone B, 14 in zone C, and 5 in ICUs. PFGE analysis revealed 7 genotypes (GTs) including 64 isolates of GT-A, 4 of GT-B, 1 of GT-C, 3 of GT-D, 1 of GT-E, 1 of GT-F, and 1 of GT-G (Figure). None had the same GT with those obtained from clinical *P. aeruginosa* bacteremia by PFGE analysis. No common source of the major strain of *P. aeruginosa* was identified by risk factor analysis. Conclusions: Colonization of *P. aeruginosa* was identified. Complying with the guideline of disinfection of HD machine and regular sampling of HD are important.

**IMPACT OF SURGICAL SITE INFECTIONS ON COST OF ILLNESS AND LENGTH OF STAY IN A TEACHING HOSPITAL**

Qun Wang, Chenrong Mi, Yibo Zhang, Wenhui Li, Gui-ting Xu, Dake Shi, Yuxing Ni. Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, PR China

**Purpose**: Economic evaluation has become increasingly important in healthcare and infection control. This study evaluate the impact of surgical site infections on cost of illness and length of stay (LOS) in a teaching hospital.

**Methods**: A retrospective study was conducted among the patients discharged from April 1st, 2014 to June 30th, 2014. The main outcomes were the total length of stay, postoperative length of stay, total cost and the antibiotics cost during hospitalization.

**Results**: 69 patients were developed an SSI after operation surgery among the patients discharged from April 1st, 2014 to June 30th, 2014, and a total of 4080 patients were performed surgical procedures at the units that developed SSI. The median total LOS of patients with episodes SSI was 30 days [95% confidence interval (CI): 24-34 days] and the median total cost of patients episodes with SSI was 75967 RMB [95% confidence interval (CI): 51006-88330 RMB].

<table>
<thead>
<tr>
<th>Table The LOS and Cost During Hospitalization</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-SSI (n=4011)</td>
</tr>
<tr>
<td>SSI (n=69)</td>

<tr>
<td>-------------------------------</td>
</tr>
<tr>
<td>Total LOS (days)</td>
</tr>
<tr>
<td>Postoperative LOS (days)</td>
</tr>
<tr>
<td>Total cost (RMB)</td>
</tr>
<tr>
<td>Antibiotics cost (RMB)</td>
</tr>
</tbody>
</table>

Conclusions: SSI causes the increased LOS and economic burden. Effective infection control measures could improve both clinical outcomes and save healthcare resources.

**MOLECULAR EPIDEMIOLOGY OF HYPERVERSULENT CLOSTRIDIUM DIFFICILE STRAINS IN SOUTHERN TAIWAN**

Hsiao-Ju Lin, Yuan-Pin Hung, Pei-Jane Tsai, Wen-Chien Ko. *a*Departments of Internal Medicine, Tainan Hospital, Department of Health, Executive Yuan, Tainan, Taiwan; *b*Departments of Medical Laboratory Science and Biotechnology, National Cheng Kung University Medical College, Tainan, Taiwan; *c*Department of Internal Medicine and Center for Infection Control, National Cheng Kung University Medical College and Hospital, Tainan, Taiwan

**Purpose**: Hypervirulent *Clostridium difficile* strains, such as polymerase chain reaction (PCR)-ribotypes 027, 078, and 106, were noted in North American and European. However, the clinical epidemiology of hypervirulent *C. difficile* in Taiwan remains unclear.

**Methods**: We conducted a 2-year prospective study in medical wards in a district hospital in southern Taiwan. Stool sample within 48 hours of admission, weekly, and at the onset of diarrhea from hospitalized patients were obtained to detect fecal *C. difficile*. Multiplex PCR and tcdC sequencing were performed to identify hypervirulent strains. 16S-23S ribotype and gyrB sequencing were done.

**Results**: Total 251 clinical *C. difficile* isolates were eligible for the study, and of them, 18 were possible hypervirulent strains, which were defined as tcdC deletion, existence of binary toxins or fluoroquinolone resistance. Analysis of these strains, PCR ribotypes 027 (3/18), 078 (1/18), 126 (4/18), 127 (6/18), and 328 (1/18) were present. The remaining 3 isolates comprised undefined ribotypes. Of these 18 hypervirulent strains, 15 showed gyr mutation. Two-thirds of those strains showed the substitution Thr82-to-Ile in gyrA and gyrB sequencing were done.

**Conclusions**: Most clinical *C. difficile* isolates were eligible for the study, and of them, 18 were possible hypervirulent strains, which were defined as tcdC deletion, existence of binary toxins or fluoroquinolone resistance. Analysis of these strains, PCR ribotypes 027 (3/18), 078 (1/18), 126 (4/18), 127 (6/18), and 328 (1/18) were present. The remaining 3 isolates comprised undefined ribotypes. Of these 18 hypervirulent strains, 15 showed gyr mutation. Two-thirds of those strains showed the substitution Thr82-to-Ile in gyrA, and most of them were PCR-126 or 127. Conclusions: The majority of the hypervirulent strains in southern Taiwan belonged to PCR-ribotype 126 or 127, not PCR-ribotype 027. The presence of mutation in codon 82 of gyrA was the most frequently found in fluoroquinolone resistance.

**INVESTIGATION OF HEALTHCARE-ASSOCIATED RESISTANT STRAINS IN A REGIONAL TEACHING HOSPITAL FROM 2004 TO 2013**

Shu-Huan Huang, Yu-Shan Chuang, Cheng-Cheng Hwang. *a*Department of Laboratory Medicine, Chang Gung Memorial Hospital Keelung, Taiwan; *b*Infection Control Committee, Chang Gung Memorial Hospital Keelung, Taiwan

**Purpose**: In order to effectively control nosocomial infections a 1038 bedded regional teaching hospital, data of infected cases and associated resistant strains were collected from the informatics system of the hospital and multi-drug resistant strains were routinely monitored.
