Abstract Sealing clearance is a key factor for a metal rubber seal’s sealability. The expansion coefficient and expansion deformation in the radial direction of metal rubber have been obtained through a thermal expansion experiment of metal rubber. The influence of the elastic modulus to the sealing clearance has been analyzed theoretically. By combining the temperature and elasticity factors of metal rubber with the elastic mechanics theory, the calculation formula of the sealing clearance has been derived, and the values of the sealing clearance and the leakage rate in certain working conditions have been calculated. Experimental results are consistent with calculation results in a high degree. The calculation formula of the sealing clearance can explain the influences of the temperature and elastic modulus factors of metal rubber on the sealing clearance. It can provide guidance for the study of sealing mechanism of metal rubber seals.

1. Introduction

Seals play a crucial role in many aeronautics and astronautics devices, and their failure may result in catastrophic events, such as the Challenger disaster.1,2 Because of the easy aging of rubber, the range in which it can work in some special situations such as high temperature and high pressure is limited. A metal rubber seal is hardly competent for the seal in special situations of high temperature and high pressure in the field of aeronautics and astronautics.3,4 The application of a metal seal is limited because when it works in a high-temperature situation, its springback ability will decrease, and it needs additional resilience to improve performance. Metal rubber is made of metal wire by a special process and its interior forms a space grid structure that depends strongly on the plentiful micro springs which are arranged in a certain mode, so it has many similar characteristics between metal and normal rubber. Metal rubber shows many advantages such as resistance properties of high temperature, high pressure, high vacuum, ultralow temperature, and radiation, and if metal rubber is made of a special metal wire, it can work in corrosion environment.5 Therefore, some rubber products that could not be competent in special working conditions of aeronautics and astronautics

The variation of temperature can lead to the metal rubber’s thermal deformation. The experiment of thermal expansion can only measure the deformation in the axial direction, but the seal’s circumferential size has been fixed when it is working in the slot, so the deformation can only happen in the radial direction. If we want to study the influence of temperature on the sealing clearance, we need to calculate the radial deformation value of the seal accurately. Based on the principle of volume invariance, we can convert the deformation in the axial direction to one in the radial direction. Fig. 1 shows the schematic of a metal rubber cylinder specimen’s volume expansion.

The relationship between the deformations in the axial direction and the radial direction can be expressed as follows:

\[
\frac{\pi d_1^2}{4} (l + \Delta l) = \frac{\pi (d_1 + \Delta d_1)^2}{4} l
\]

where \(d_1\) is the metal rubber specimen’s diameter before the temperature rise; \(l\) is the metal rubber specimen’s length before the temperature rise; \(\Delta d_1\) is the metal rubber specimen’s radial increment and \(\Delta l\) is its axial increment after the temperature rise.

Therefore, the relationship between the metal rubber specimen’s coefficients of linear expansion in the radial direction and the axial direction can be expressed as follows:

\[
x_r = \sqrt{1 + x - 1}
\]

where \(x_r\) and \(x\) are the coefficients of linear expansion in the radial and axial directions, respectively.

The coefficient of linear expansion can be measured through a thermal expansion experiment. The coefficient of expansion in the axial direction can be measured by a DIL 402C thermal dilatometer produced by NETZSCH. The coefficient of expansion in the radial direction and the radial increment can be calculated. The results of calculation of radial deformation are shown in Table 1, where \(t\) is the temperature of the experiment and \(\Delta d\) is the deformation that is converted to the radial direction.

The leakage experiments of a metal rubber seal were done in a heating cabinet and the experiment would begin when the temperature of the heating cabinet was stable. We assumed that each work temperature of the metal rubber seal was constant and didn’t consider the dynamic temperature variance in system modeling.

### 2.2. Influence of elastic modulus on sealing clearance

When the working pressure of the seal increases, the medium which needs to be sealed will squeeze into the sealing clearance, at the same time the pressure of the medium will press the seal, and then the deformation of the seal leads to the sealing clearance increasing. As an elastomer, the metal rubber’s elastic modulus can influence the sealing clearance directly. The metal rubber’s elastic modulus include the friction stress modulus and the elasticity stress modulus, and because a static seal’s elasticity stress modulus is more important, the friction stress modulus is the main research object of dynamic performance of metal rubber. In this paper, we study the metal rubber seal, we only think about the elastic stress modulus. Metal rubber is a kind of anisotropic materials of which the elastic modulus doesn’t remain constant and changes with the strain’s change. Because the sealing clearance’s variation is very small, we can use the elastic modulus under the pre-compression state instead of metal rubber’s elastic modulus when it’s working.

The friction stress and elasticity stress can be calculated as follow:

\[
\sigma_1 = \frac{\sigma_{el} + \sigma_{UL}}{2}
\]

\[
\sigma_2 = \frac{\sigma_{el} - \sigma_{UL}}{2}
\]

\[
E = \frac{\sigma_1}{\varepsilon}
\]
When leakage occurs, the pressure which works on the seal and the seal face, the medium will be squeezed into the sealing clearance which leads to leakage. When leakage occurs, the pressure which works on the seal at the sealing face and leads to the seal’s deformation can be expressed as follows:

\[ P > \sigma \]  

where \( P \) is the medium pressure, \( \sigma \) is the total contact stress between the seal and the seal face, and \( \sigma_0 \) is the contact stress produced by pre-lode, and \( K \) is the pressure transfer coefficient.

In the contact area between the seal and the seal face, the contact stress is approximate to parabolic distribution, and the maximum contact stress appears at the center line. While the pressure of the medium is higher than the maximum contact stress, the metal rubber seal will generate deformation. The sealing clearance is constituted by the deformation which is caused by the medium pressure and the deformation in the radial direction is caused by thermal expansion. The sealing clearance’s calculation formula is shown as follows:

\[ h = \Delta\delta - \Delta d \]

where \( \Delta\delta \) is the deformation caused by the medium pressure and \( \Delta d \) is the value in Table 1.

The relationship between pressure and deformation in the radial direction of cylindrical metal rubber can be expressed as follows:

\[ \sigma = \sigma_0 + KP \]

\[ P_0 = P - \sigma \]

where \( P_0 \) is the pressure which leads to the seal’s deformation, \( P \) is the pressure of the medium, and \( \sigma \) is the total contact stress between the seal and the seal face, \( \sigma_0 \) is the contact stress produced by pre-lode, and \( K \) is the pressure transfer coefficient.

Because the sealing problem of this paper is from a static seal and the leakage of the seal system will lead to a decrease of system pressure. We can know from the experiment that the volume of leakage is small so the pressure variation due to the leakage is small too, and we assume that the pressure in the sealing system is equal everywhere. Therefore, we don’t consider the influence of the dynamic pressure field on the sealing clearance.

When the medium’s pressure is higher than the contact stress between the seal and the seal face, the medium will be squeezed into the sealing clearance which leads to leakage. When leakage occurs, the pressure which works on the seal at the sealing face and leads to the seal’s deformation can be expressed as follows:

\[ P > \sigma \]  

\[ \Delta\delta = \frac{(1 - v)^2 \int \frac{\sqrt{x^2 + y^2}}{\sqrt{x^2 + y^2}} P_0 \, dx \, dy}{\pi E_1} \]

where \( \Delta\delta \) is the deformation in the radial direction of cylindrical metal rubber, \( E \) is the elastic modulus of the metal rubber seal, \( 2a \) is the contact width between the seal and the seal face, and \( v \) is the metal rubber’s Poisson’s ratio.

The metal rubber seal is working in a slot, so its circumferential size has been fixed. Because of this, Poisson’s ratio of the metal rubber seal can be ignored, so Eq. (10) can be transformed to the following equation:

\[ \Delta\delta = \frac{(P - \sigma_0 - KP)\lambda_1 \int \frac{\sqrt{x^2 + y^2}}{\sqrt{x^2 + y^2}} P_0 \, dx \, dy}{\pi E_1} \]

where \( E_1 \) is the elastic modulus when the metal rubber seal’s deformation is 0.75 mm, and \( \lambda_1 \) is the shape coefficient of the metal rubber seal in the pre-compression state.

From the above, thinking about the influence of pressure on thermal deformation introduces a coefficient \( \lambda_2 \), so we obtain the calculation formula of seal clearance as follows:

\[ h = \frac{(P - \sigma_0 - KP)\lambda_1 \int \frac{\sqrt{x^2 + y^2}}{\sqrt{x^2 + y^2}} P_0 \, dx \, dy}{\pi E_1} - \lambda_2 \Delta d \]
we can obtain are both sides of the sealing surface, clearance per unit time), viscosity of the medium under room temperature, and the friction stress as the value of double integral is 0.00963, k = 2.8 mm, and the size of contact area has been changed to R0 = 70.15 mm and R1 = 68.05 mm. While the pre-deformation is 0.5 mm, by the hysteresis loop, we can get the elastic stress as σ1 = 1.245 MPa and the friction stress as σ2 = 0.422 MPa. In addition, the calculation result of the elastic modulus is E1 = 7.968 MPa. We also choose the TOTAL HYDRANSAFE HFDU 46 as the medium, and its dynamic viscosity is μ0 = 0.431 Pa·s. The experiment of metal rubber seal leakage has been done in normal temperature, and the results we get are the sealing clearance and leakage rate at different pressure conditions, as shown in Table 2. In Table 2, q1 is the value of theoretical calculation and q is the value of test.

4.2. Calculation under different temperature conditions

We only change the pre-deformation to δ = 0.5 mm, then the contact width to 2a = 2.1 mm, and the size of contact area has been changed to R0 = 70.15 mm and R1 = 68.05 mm. While the pre-deformation is 0.5 mm, by the hysteresis loop, we can get the elastic stress as σ1 = 1.245 MPa and the friction stress as σ2 = 0.422 MPa. In addition, the calculation result of the elastic modulus is E1 = 7.968 MPa. We also choose the TOTAL HYDRANSAFE HFDU 46 as the medium, while in the experiment of metal rubber seal leakage, we keep the pressure as P = 14 MPa and then change the temperature. The results of calculation and experiment are shown in Table 3 as follows. In Table 3, q1 is the value of theoretical calculation and q is the value of test. We compare the results of calculation and experiment finding that the leakage rate of theoretical calculation coincides with the experiment result roughly. The inaccuracy between testing and theoretical calculation was caused by the inaccuracy of the sensor which was inevitable. During the process of formula deduction, we proposed some hypothesis and for simplifying the formula, we ignored some factors that were not important. That’s why there are errors between the results of experiment and theoretical calculation. It is proven that the formula of sealing clearance calculation which has been deduced in this paper can be used in the leakage rate analysis of metal rubber sealing systems.

5. Conclusions

In this paper, the influence factors that result in the change of the sealing clearance at the work process of a metal rubber seal cladded with stainless steel have been analyzed. A thermal expansion experiment has been done, through which we know that the radial expansion of metal rubber increases with the
increase of temperature and then leads to a decrease of the sealing clearance; the elastic modulus of metal rubber is nonlinear, and the larger elastic modulus of metal rubber, the more difficulty for the increase of the sealing clearance. In this paper, the calculation formula of the sealing clearance has been derived, and we calculate the sealing clearance and leakage rate of the metal rubber seal with that formula. We compare the results of calculation and experiment and have found that the leakage rate of theoretical calculation coincides with the experiment result roughly. The sealing clearance is a very important parameter for the calculation of leakage, and the calculation formula that we derived can provide some theoretical basis for the design of metal rubber seals which can work in special environments.
