Photocatalysis

**Abstract** A series of graphitic carbon nitride/silver carbonate ( $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ ) rod-like composites with different weight contents of  $\text{g-C}_3\text{N}_4$  have been prepared by a facile precipitation method. The  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  rod-like composites exhibited higher photocatalytic activity than pure  $\text{Ag}_2\text{CO}_3$  toward degradation of rhodamine B (RhB) and methylene blue (MB) under visible-light irradiation. The photocatalytic reaction follows a pseudo-first-order reaction and the rate constants for the degradation of RhB and MB by 3.5%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  are about 2 times and 1.7 times that of pure  $\text{Ag}_2\text{CO}_3$ , respectively. A possible photocatalytic mechanism was proposed based on the photoluminescence (PL) spectra and a series of radical trapping experimental analyses. The remarkably improved photocatalytic performance should be ascribed to the heterostructure between  $\text{Ag}_2\text{CO}_3$  and  $\text{g-C}_3\text{N}_4$ , which greatly promoted the photoinduced charge transfer and inhibited the recombination of electrons and holes.

## 1. Introduction

Photocatalytic activity of the materials depends on the efficient separation of the photogenerated electrons and holes. The critical points for a good semiconductor photocatalysis are the high efficiency separation of photoexcited electron-hole pairs, the decrease of electron-hole recombination and good repeatability of photocatalysts. Recently, nanostructured materials have attracted considerable interest owing to their unique properties and potential applications [1–3]. Therefore, the decomposition of organic pollutants using various nanomaterials in the presence of sunlight has been a major topic.  $\text{TiO}_2$  is one of the most effective photocatalysts for the degradation of organic pollutants as well as other toxic materials under

ultraviolet (UV) light irradiation. On the other hand,  $\text{TiO}_2$  is a wide band gap semiconductor (3.02 eV for rutile and 3.18 eV for anatase) [4], which means that it can absorb only 5% of sunlight in the UV region, limiting its practical applications. Nanocomposites can improve the visible light photocatalytic activities of wide band gap semiconductors. For example, Cho et al. developed  $\text{TiO}_2$  nanoparticles,  $\text{Au@TiO}_2$  and  $\text{Ag@TiO}_2$  nanocomposites for the catalytic degradation of dyes under visible light irradiation [5–7]. Therefore, a significantly efficient, stable, inexpensive, easily separable semiconductor material that works well with visible light is a major challenge in this field [8,9].

Silver carbonate ( $\text{Ag}_2\text{CO}_3$ ), a narrow band gap semiconductor, has been widely used for photocatalytic degradation of organic contaminations (e.g., rhodamine B (RhB), methylene blue (MB), methyl orange (MO) dyes and phenol) and photocatalytic destruction of *Escherichia coli* under visible-light illumination [10–12]. In general, photocatalytic activity can be improved by preparing silver-based compounds with different means, such as morphology control, size control, modification, and hybridization. More recently, graphene oxide- $\text{Ag}_2\text{CO}_3$  composite reported by our group showed higher visible-light photocatalytic activity than the bare  $\text{Ag}_2\text{CO}_3$  under identical condition [13]. Here, graphene oxide used as a support can be replaced by other two dimensional materials.

In 2009, a great breakthrough was made by Wang and co-workers, who reported a new use of graphitic carbon nitride ( $\text{g-C}_3\text{N}_4$ ) semiconductor, which can produce hydrogen from water under visible-light irradiation [14]. After that, numerous  $\text{g-C}_3\text{N}_4$ /silver-based semiconductor hybrid photocatalysts have been extensively reported, such as the composites of  $\text{g-C}_3\text{N}_4/\text{Ag}_3\text{VO}_4$  [15],  $\text{g-C}_3\text{N}_4/\text{Ag}_3\text{PO}_4$  [16],  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{O}$  [17], and  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composites [18–21]. The  $\text{g-C}_3\text{N}_4$  partly modified with  $\text{Ag}_3\text{VO}_4$ ,  $\text{Ag}_3\text{PO}_4$ ,  $\text{Ag}_2\text{O}$ , and  $\text{Ag}_2\text{CO}_3$  exhibited remarkably enhanced photocatalytic performances. Herein, a facile precipitation method was developed to prepare a series of  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  rod-like composites for the first time. Compared with the pure  $\text{Ag}_2\text{CO}_3$ , the novel  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  hybrid photocatalysts possessed higher photocatalytic activity toward the degradation of RhB and MB under visible-light irradiation.

## 2. Experimental section

### 2.1. Synthesis of $\text{g-C}_3\text{N}_4$

The  $\text{g-C}_3\text{N}_4$  powder was synthesized according to the literature [22]. Typically, 10 g of melamine was put into an alumina crucible with a cover and heated at a rate of  $20\text{ }^\circ\text{C min}^{-1}$  to  $550\text{ }^\circ\text{C}$  in a muffle furnace and then kept at this temperature for 4 h. All the experiments were performed under air conditions. The resulting yellow product was collected and ground into powder for further use.

### 2.2. Synthesis of $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ composites

Typically, 20 mL  $\text{g-C}_3\text{N}_4$  dispersions with different concentrations (0.1, 0.25, 0.35, 0.5 and 1 mg/mL) were treated with ultrasonic for 2 h, then 5 mL aqueous solution of  $\text{AgNO}_3$  (0.2 M) was added under magnetic stirring, and then kept

stirring for another 1 h in the dark. At last, 5 mL aqueous solution of  $\text{NaHCO}_3$  (0.1 M) was added dropwise into the above mixture under magnetic stirring, and then kept stirring for additional 12 h in the dark. The final products were collected by centrifugation, washed with de-ionized water and absolute ethanol several times and dried in vacuum at room temperature for 24 h. For convenience, the as-prepared composites with different weight contents of  $\text{g-C}_3\text{N}_4$  were labeled by 1.4%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , 3.5%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , 4.8%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , 6.8%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  and 12.7%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , respectively. The pure  $\text{Ag}_2\text{CO}_3$  was synthesized via a parallel process but without  $\text{g-C}_3\text{N}_4$ .

### 2.3. Characterization

Structure and morphology of the products were characterized by X-ray powder diffraction (XRD, Philips X'Pert PRO), scanning electron microscopy (SEM, Hitachi S-4800), and high-resolution transmission electron microscopy (TEM, JEOL-2010 TEM with an acceleration voltage of 200 kV), respectively. UV–visible diffuse reflectance spectra (DRS) were recorded by a Shimadzu UV-2450 spectrometer using  $\text{MgO}$  (light) as a standard at room temperature. The photoluminescence (PL) spectra for solid samples dispersed in absolute ethanol were investigated with an excitation wavelength of 320 nm on a Hitachi F-4500 fluorescence spectrophotometer.

### 2.4. Photocatalytic evaluation

The optical system for the photocatalytic reaction was composed of a 500 W Xe lamp (Shanghai Jiguang Special Light, China) and a cutoff filter ( $\lambda > 400\text{ nm}$ ). RhB or MB aqueous solution (30 mL, 10 mg/L) containing 20 mg of catalyst was put in a sealed glass beaker and first ultrasonicated for several minutes, and then stirred in the dark for 1 h to ensure absorption–desorption equilibrium. After visible-light illumination at regular time intervals, the absorbance of dye solution was monitored by a Hitachi U-3010 UV–vis spectrophotometer.

## 3. Results and discussion

The structure information of the as-prepared products was collected by XRD. Fig. 1(I) shows a typical XRD pattern of pure  $\text{Ag}_2\text{CO}_3$ . All the diffraction peaks can be well-indexed to a monoclinic crystalline phase  $\text{Ag}_2\text{CO}_3$  (JCPDS No. 12-0766). The XRD pattern of pure  $\text{g-C}_3\text{N}_4$  is displayed in Fig. 1(VII), the strongest peak at  $27.5^\circ$  corresponding to the (002) plane arising from the stacking of the conjugated aromatic system and the other peak at  $13.1^\circ$  corresponding to the (100) plane are associated with interlayer stacking [16–18]. We also found that the XRD patterns of  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composites were similar to those of pure  $\text{Ag}_2\text{CO}_3$  (Fig. 1(II)–(IV)), but with the increasing weight contents of  $\text{g-C}_3\text{N}_4$ , the characteristic peak of  $\text{g-C}_3\text{N}_4$  gradually appears (Fig. 1(V) and (VI)). Therefore, the formation of  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composites has been proved.

The morphology of the products was studied by SEM. Fig. 2(a) shows a SEM image of pure  $\text{Ag}_2\text{CO}_3$ , which was composed of straight and smooth rod with ca. 500 nm in diameter and  $2\text{ }\mu\text{m}$  in length. The SEM image of  $\text{g-C}_3\text{N}_4$  sheets is also given in Fig. S1 (see ESI). From Fig. 2(b)–(f), we can

**Figure 1** XRD patterns of (I)  $\text{Ag}_2\text{CO}_3$ , (II) 1.4%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , (III) 3.5%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , (IV) 4.8%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , (V) 6.8%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , (VI) 12.7%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , and (VII)  $\text{g-C}_3\text{N}_4$ .

see that  $\text{Ag}_2\text{CO}_3$  rods are randomly deposited on the  $\text{g-C}_3\text{N}_4$  sheets. We believe that the hybridization of  $\text{Ag}_2\text{CO}_3$  with  $\text{g-C}_3\text{N}_4$  is beneficial to the synergistic interaction between  $\text{Ag}_2\text{CO}_3$  rods and  $\text{g-C}_3\text{N}_4$  sheets. The morphology of the  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composite was also investigated by TEM. Fig. S2 (see ESI) shows the TEM images of the 3.5%

$\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  sample. From the TEM image of  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  sample, it can be seen that  $\text{g-C}_3\text{N}_4$  was successfully dispersed on the surface of  $\text{Ag}_2\text{CO}_3$  and the heterostructure between  $\text{g-C}_3\text{N}_4$  and  $\text{Ag}_2\text{CO}_3$  was formed in the  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composite.

The optical absorbance of the as-obtained samples was measured by UV-vis diffuse reflectance spectroscopy (Fig. S3(a)). The absorption spectrum of  $\text{Ag}_2\text{CO}_3$  extends from UV to visible region (480 nm). After being modified by  $\text{g-C}_3\text{N}_4$ , the color of the  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composites changed from dark yellow to bright yellow (inset Fig. S3(a)) and there is an enhanced absorbance in the visible-light region ranging from 480 to 800 nm. Fig. S3(b) shows the plots of the transformed Kubelka-Munk function of light energy  $(xh\nu)^{1/2}$  versus energy  $(h\nu)$  for the as-prepared samples.  $\text{Ag}_2\text{CO}_3$  belongs to indirect band gap semiconductor and its band gap is estimated to be 2.34 eV, which is close to the values in the previous reports [10–12]. The band gaps of  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composites are also calculated to be 2.18, 2.12, 2.17, 2.23, 2.29 eV, respectively, as displayed in Table 1. This indicates a band gap narrowing of the semiconductor  $\text{Ag}_2\text{CO}_3$  due to the introduction of  $\text{g-C}_3\text{N}_4$  into the matrix of  $\text{Ag}_2\text{CO}_3$ , which can be attributed to the synergistic interaction between semiconductor and  $\text{g-C}_3\text{N}_4$  support. Furthermore, the absorption edge of the pure  $\text{g-C}_3\text{N}_4$  is at about 470 nm, which originates from its band gap

**Figure 2** SEM images of (a)  $\text{Ag}_2\text{CO}_3$ , (b) 1.4%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , (c) 3.5%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , (d) 4.8%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , (e) 6.8%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ , and (f) 12.7%  $\text{g-C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$ .

**Table 1** The band gaps ( $E_g$ ) and first-order rate constants ( $k$ ) of the as-prepared samples.

Samples	$E_g$ (eV)	$k$ ( $\text{min}^{-1}$ )	
		RhB	MB
$\text{Ag}_2\text{CO}_3$	2.34	0.04413	0.06703
1.4% g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$	2.18	0.05675	0.06968
3.5% g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$	2.12	0.08603	0.11112
4.8% g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$	2.17	0.07328	0.09177
6.8% g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$	2.23	0.04144	0.04941
12.7% g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$	2.29	0.03058	0.02871
g- $\text{C}_3\text{N}_4$	2.63	0.00579	0.00722

of  $\sim 2.63$  eV and is consistent with the reported results [16,17,22].

The photocatalytic performance of  $\text{Ag}_2\text{CO}_3$ , g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composites and g- $\text{C}_3\text{N}_4$  is evaluated by the degradation of RhB and MB under visible-light irradiation. As shown in Figs. 3, S4 and S5, the degradation efficiency of RhB and MB follows the order 3.5% g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3 > 4.8\%$  g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3 > 1.4\%$  g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3 > \text{Ag}_2\text{CO}_3 > 6.8\%$  g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3 > 12.7\%$  g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3 > \text{Ag}_2\text{CO}_3 > \text{g-}\text{C}_3\text{N}_4$ . Obviously, the addition of an appropriate amount of g- $\text{C}_3\text{N}_4$  can enhance the photocatalytic activity effectively. However, superfluous g- $\text{C}_3\text{N}_4$  will decrease photocatalytic performance, indicating a synergistic interaction between g- $\text{C}_3\text{N}_4$  sheets and  $\text{Ag}_2\text{CO}_3$  rods is required in order to improve the photoactivity of semiconductor  $\text{Ag}_2\text{CO}_3$  rods. The optimal weight content of g- $\text{C}_3\text{N}_4$  in this study is 3.5%. Assuming that the photocatalytic reaction follows a pseudo-first-order reaction due to low concentration of the dye solutions, the relevant equations are listed as follows:  $-\ln(C_t/C_0) = kt$ , where  $C_0$  and  $C_t$  are the concentrations of reactant at time 0 and  $t$ , respectively, and  $k$  is the first-order reaction rate constant [23,24]. The corresponding first-order rate constants are shown in Fig. S6 and listed in Table 1. It is noted that the degradation rate constants for MB by g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composites are higher than those for RhB on the general trend, which indicates that MB is more easily degraded under the same conditions. Significantly, the first-order rate constants for the degradation of RhB and MB by 3.5% g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  are 0.08603 and 0.11112  $\text{min}^{-1}$ , respectively, which are about 2 times and 1.7 times that of pure  $\text{Ag}_2\text{CO}_3$  (0.04413 and 0.06703  $\text{min}^{-1}$ ).

As is known to all, the behavior of photogenerated charge carriers is a key factor to determine the performance of photocatalysts [25]. The separation and lifetime of photogenerated electron-hole pairs can be confirmed by the PL spectra. The PL intensity with higher value means more recombination of electron-hole pairs and lower photocatalytic activity [15]. As displayed in Fig. S7, under excitation wavelength of 320 nm, for g- $\text{C}_3\text{N}_4$  sheets, a strong emission peak at about 465 nm is detected. The PL peak intensity of 3.5% g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composite is close to pure  $\text{Ag}_2\text{CO}_3$ , but dramatically decreases compared with g- $\text{C}_3\text{N}_4$ . However, the band gap of 3.5% g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composite is narrower than  $\text{Ag}_2\text{CO}_3$  as well as g- $\text{C}_3\text{N}_4$ , leading to a more light harvest, thus further improving its photoactivity. As a result, both the band gap of photocatalyst and the separation of electron-hole pairs have an influence on the performance of the photocatalyst.

**Figure 3** Photocatalytic activities of as-prepared photocatalysts for degradation of (a) RhB and (b) MB under visible-light irradiation.

In the photodegradation process, some active species including holes ( $h^+$ ), hydroxyl radicals ( $\cdot\text{OH}$ ) and superoxide radicals ( $\cdot\text{O}_2^-$ ) were formed by light irradiation.  $\cdot\text{O}_2^-$  was formed by direct reduction of  $\text{O}_2$  with electron [19,21]. The  $\cdot\text{OH}$  was obtained by the direct hole oxidation or photogenerated electron induced multistep reductions of  $\cdot\text{O}_2^-$ . Furthermore, holes could directly react with organic compounds if the photocatalyst has moderate redox potential. Therefore, in order to understand the interaction between  $\text{Ag}_2\text{CO}_3$  and g- $\text{C}_3\text{N}_4$ , the active species generated during the photodegradation process over g- $\text{C}_3\text{N}_4$ ,  $\text{Ag}_2\text{CO}_3$  and g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  can be identified by active species scavenging experiments. In the previous report, the trapping experiments of free radicals and holes were carried out by Li etc. to investigate the main reactive species for degradation of MO and RhB by g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composite [21]. They found that the degradation rate of MO decelerated obviously after the addition of disodium ethylenediaminetetraacetate (EDTA) or 1,4-benzoquinone (BQ). However, the degradation rate showed almost no change in the presence of tert-butyl alcohol (t-BuOH), suggesting that the holes and  $\cdot\text{O}_2^-$  are the main reactive species for degradation of MO. For the degradation of RhB, the photocatalytic activity decreased slightly after the addition of t-BuOH. However, it is inhibited greatly in the presence of EDTA and BQ, indicating that the holes and  $\cdot\text{O}_2^-$  also play a major role in the degradation of RhB [19–21].

Based on the above analyses and the related literature reports, the possible mechanism of the enhanced photocatalytic activity of the g- $\text{C}_3\text{N}_4/\text{Ag}_2\text{CO}_3$  composites was proposed and shown in Fig. 4. Under visible light irradiation, both g- $\text{C}_3\text{N}_4$  and  $\text{Ag}_2\text{CO}_3$  could absorb visible light and were all

**Figure 4** Band structure diagram and electron-hole separation of g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> composite.

excited to generate electron and hole pairs. The holes on the surfaces of g-C<sub>3</sub>N<sub>4</sub> and Ag<sub>2</sub>CO<sub>3</sub> could directly decompose the RhB molecules into the intermediates. g-C<sub>3</sub>N<sub>4</sub> has a more negative potential of the conduction band (CB) and valence band (VB) than that of Ag<sub>2</sub>CO<sub>3</sub>. Therefore, the excited electrons on g-C<sub>3</sub>N<sub>4</sub> could directly be injected into the CB of Ag<sub>2</sub>CO<sub>3</sub>, meanwhile the holes could migrate from the VB of Ag<sub>2</sub>CO<sub>3</sub> to that of g-C<sub>3</sub>N<sub>4</sub>, which promotes the effective separation of photoexcited electrons and holes. As a result, the enriched electrons on the CB of Ag<sub>2</sub>CO<sub>3</sub> will react with oxygen to generate  $\cdot\text{O}_2^-$ . The  $\cdot\text{O}_2^-$  active species together with the holes on the VB of g-C<sub>3</sub>N<sub>4</sub> are responsible for the degradation of organic pollutants.

The stability and reusability of catalysts are very important issues for practical applications. The g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> composite could be readily recycled by simple centrifugation after reaction. The stability and reusability of the 3.5% g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> composite were examined by repetitive use of the catalyst. As shown in Fig. S8 (see ESI), the catalyst exhibited a little loss of activity after three photodegradation cycles of RhB. However, it still kept high photocatalytic activity after three photodegradation cycles of RhB, indicating its excellent stability and great potential value in environmental purification. g-C<sub>3</sub>N<sub>4</sub> possesses a conjugated  $\pi$  structure, which has been proven to effectively suppress photocorrosion during the g-C<sub>3</sub>N<sub>4</sub> based photocatalytic reaction [26].

The photocatalyst after the reusability experiments was further analyzed by SEM and XRD to study the photostability of 3.5% g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> composite. The SEM image of the spent sample (Fig. S9, see ESI) was found to be the same morphologies as those of the fresh sample. Fig. S10 (see ESI) shows the XRD patterns of 3.5% g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> composite before and after degradation of RhB. After three catalytic runs, the peak positions had no obvious changes. However, the XRD analysis of the sample (three cycling runs) indicated that the intensity of recycled 3.5% g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> sample decreased and the diffraction peak at  $2\theta$  values 38.1° was assigned to the (111) lattice plane of Ag nanoparticles [18,19,27,28]. In order to further confirm the existence of Ag after the photodegradation, Shi etc. checked the spent

g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> composite by X-ray photoelectron spectroscopy (XPS). Compared with the fresh g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> composite, Ag 3d peak showed a larger full width at half maximum. And Ag 3d<sub>5/2</sub> and 3d<sub>3/2</sub> peak could be further divided into two different peaks. The peaks at 368.9 and 374.8 eV were assigned to metallic Ag (0). The results suggested that partial Ag<sub>2</sub>CO<sub>3</sub> was reduced to Ag in the process of photocatalytic reaction [19,21]. So during the photocatalytic reaction, the g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> system was transformed to be g-C<sub>3</sub>N<sub>4</sub>/Ag/Ag<sub>2</sub>CO<sub>3</sub> system. There are two reasons to explain the decreasing photocatalytic activity of the g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> composite after three cycling runs. One reason is that the Ag nanoparticles gradually formed on the Ag<sub>2</sub>CO<sub>3</sub> surface under the photocatalytic reaction process, which prevents the light absorption of Ag<sub>2</sub>CO<sub>3</sub>. Another reason is that the formed Ag nanoparticles also serve as the capture center of the electrons and holes.

#### 4. Conclusions

In summary, we have developed a simple precipitation method for the preparation of g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> composites with different weight contents of g-C<sub>3</sub>N<sub>4</sub>. The 3.5% g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> photocatalyst exhibited higher photocatalytic activity for RhB and MB degradation under visible light irradiation than bare Ag<sub>2</sub>CO<sub>3</sub> rods. The enhanced photocatalytic activity should be attributed to the efficient separation of photoinduced charge carriers resulted from effective fabrication of g-C<sub>3</sub>N<sub>4</sub>/Ag<sub>2</sub>CO<sub>3</sub> heterojunction, as confirmed by the PL spectra. This work might provide a simple and high-efficient approach for removal of organic pollutants by using solar energy.
