400-600 million in direct medical costs and up to $2 billion from treatment-induced reduction in infant mortality. CONCLUSIONS: Feeding extremely preterm infants with an exclusively human-milk based diet (fortified with Prolacta HMF®) is highly cost-effective in the prevention of NEC as compared to feeding human-milk fortified with bovine-milk based supplements.

**IMPACT OF SEVERITY DIFFERENCES ON LOGICAL INCONSISTENCIES IN VALUES FOR EQ-SD HEALTH STATES**

Jaundhwala Y, Shaw JW, Pickard AS, Walton S, Busschbach J

1University of Illinois at Chicago, Chicago, IL, USA, 2University of Illinois at Chicago, Chicago, IL, USA, 3Erasmus MC, Rotterdam, The Netherlands

OBJECTIVES: The values assigned to EQ-SD health states may be inconsistent with their logical severity. A logical inconsistency occurs when a health state is logically more severe than another but receives a lower value. The objective of this research was to determine whether logical inconsistencies are related to differences in the severity of paired health states. METHODS: One hundred twenty-six Dutch university students used visual analog scales to value the 243 EQ-SD health states. Logical inconsistency rates were estimated for 55 pairs of health states over 1,000 randomly generated vectors of 11 states. Multiple logistic regression was used to model the logical inconsistency of paired health state values as a function of between-state differences in the severity of specific dimensions. RESULTS: Over the 1,000 health state vectors, mean inconsistency rates for paired low-, moderate-, and high-severity states were 0.011, 0.220, and 0.045, respectively. Average inconsistency rates for paired moderate-severity states differed from the average rates for paired low-severity states (p < 0.001) and high-severity states (p < 0.05) for each EQ-SD dimension. The probability of logical inconsistency was positively related to the similarity of the paired states with respect to health problems. The probability of logical inconsistency was higher when both states had moderate or extreme problems in a given dimension than without problems. CONCLUSIONS: The probability of inconsistent valuation increases with the similarity of the paired states and is higher when both states are moderately severe than otherwise. These findings have implications for the selection of health states in population-based valuation studies.

**THE PSYCHOMETRIC PROPERTIES OF THE PERCEPTIONS OF CARE ADJECTIVE CHECK LIST–REVISED (PCACL-R) EVALUATED IN A LARGE UK MATERNITY CARE POPULATION**

Redshaw M, Marian C

1University of Oxford, Oxford, UK, 2University of the West of Scotland, Ayr, UK

OBJECTIVES: To develop and validate a novel assessment tool for the assessment of perceived care quality of women’s experiences of maternity care. The current study reports the psychometric properties of the developed Perceptions of Care Adjective Check List–Revised (PCACL-R). METHODS: Data were collected from a UK national survey of women’s experiences of maternity care (n = 2960). Confirmatory factor analysis, convergent validity analysis, convergent validity analysis, predictive validity, and internal consistency approaches were used to evaluate the psychometric properties of the tool. RESULTS: Confirmatory factor analysis demonstrated a good fit to a bi-dimensional structure entirely consistent with the negative and positive valencing of adjectives, which is consistent with the use of the tool as a two (negative, positive) sub-scale tool. The PCACL-R revealed good convergent validity and excellent divergent validity characteristics. Discriminant validity was assessed against measures of maternal deprivation, partner status and type of delivery and revealed good discriminant validity of the PCACL-R. Internal consistency characteristics of the two PCACL-R sub-scales were acceptable. The predictive validity of the PCACL-R was also excellent. CONCLUSIONS: The PCACL-R is recommended as a valid, reliable, respondent acceptable and easy to administer instrument to assess women’s experiences of their maternity care.

**VALIDATION AND COMPARISON OF EUROQOL AND SHORT FORM 6D IN CHINESE CHRONIC PROSTATISIS PATIENTS**

1University of Newcastle, Callaghan, N.S.W., Australia, 2Hospital of PLA, Beijing, Beijing, China

OBJECTIVES: Generic, preference-based Health-related Quality of Life (HRQoL) instruments are increasingly used in decision-making process of clinicians and policymakers. However, no such HRQoL instrument has been validated or used in Chronic Prostatitis (CP), in which a goal of patient management is to improve the HRQoL. We therefore aimed to assess and compare the psychometric properties of EuroQol EQ-5D and Short Form 6D (SF-6D) among CP patients in China. METHODS: Consenting CP patients were interviewed using EQ-5D and SF-6D. Convergent and discriminant construct validities were examined with five and two a priori hypotheses respectively. Sensitivity was compared using receiver operating characteristic (ROC) curves. Relative efficiency (RE) statistics were used to evaluate the effectiveness of intervention programs. Agreement between instruments was assessed with intra-class correlation coefficients (ICCs) and Bland-Altman plot, while factors affecting utility difference were explored with multiple linear regression models. RESULTS: In 268 CP patients (median age 32 years) who completed the interview, mean ± SD EQ-5D and SF-6D utility scores were comparable at 0.74 ± 0.13 and 0.75 ± 0.09 respectively. Five of the seven hypotheses for construct validity were fulfilled in both instruments. The areas under ROC all exceeded 0.5 (p < 0.001), suggesting that the instruments are sensitive to detect clinically relevant differences in CP patients, with both EQ-5D having 9.7–19.9% higher efficiency at detecting differences in CP symptom severity. Despite no significant difference in paired comparisons of utility scores between the 2 instruments, lack of agreement was observed with low ICC (0.218– 0.630) and Bland-Altman plot analysis. CP symptom severity significantly (p < 0.05) improved differences in utility scores between EQ-5D and SF-6D. CONCLUSIONS: EQ-5D and SF-6D are demonstrated to be valid and sensitive HRQoL measures in Chinese CP patients, with SF-6D showing better HRQoL dimension coverage, greater sensitivity and lower ceiling effect. Further research is needed to determine other psychometric properties, such as longitudinal response and reliability.

**CONSTRUCT VALIDITY OF THE BENIGN PROSTATIC HYPERPLASIA IMPACT INDEX**

Angkaludhiti M, Seifert RF, Hayes V, Vatrapur L

1Bi Lily & Co, Indianapolis, IN, USA, 2Lewin Group, 3Innovus, Falls Church, VA, USA

OBJECTIVES: To demonstrate the construct validity of the Benign Prostatic Hyperplasia Impact Index (BPII). METHODS: Data from two Tadalafil multi-center, double-blind, placebo-controlled Phase II clinical trials of men 45 years of age or older with moderate to severe BPH and evidence of bladder obstruction (N = 281; N = 1053) were included in this analysis. Measures included BII, International Prostate Symptom Score (IPSS), IPSS-Quality of Life Index (IPSS QOL), Lower Urinary Tract Symptoms Global Assessment Question (LUTS-GAQ), uroflowmetry measure peak flow rate (Qmax) and postvoid residual volume (PVR). Data from each study were analyzed separately. Pearson correlation coefficients were computed between the BII scores across visits and the other measures. T-tests and general linear modeling compared BII scores of subjects with global ratings of improvement versus no improvement, and between subjects taking Tadalafil versus placebo. RESULTS: There were strong correlations of BII with subjective measures (IPSS, IPSS QOL, LUTS-GAQ) and low correlations of BII with objective measures (Qmax, PVR) were observed in this analysis. There were also statistically significant differences in BII at the End-of-Study Visit between subjects who improved versus subjects with no improvement (Studies 1 and 2, p < .0001) and between subjects taking Tadalafil versus subjects taking placebo (Study 1, p = .0088; Study 2, p = .0092). CONCLUSIONS: Results demonstrate that BII is reliable and has construct validity. BII is well correlated with subjective measures and less correlated with objective measures, which is confirmatory of literature findings. It is a valuable measure of the impact of BPH symptoms on health and functioning that can be useful in determining treatment options and outcomes for men with BPH.

**OVERVIEW OF THE DEVELOPMENT PHASES OF THE OXFORD ANKLE FOOT QUESTIONNAIRE FOR CHILDREN**

OBJECTIVES: Ankle and foot problems are a common reason for children to present in clinic. The Oxford Ankle Foot Questionnaire for Children was designed to supplement existing measures and to enable scales to be developed; three scales were identified and shown to be valid and reliable: Physical (6 items), Emotional (4 items), and School & Play (4 items). Finally, a prospective study was conducted with trauma and elective patients to assess how the scale changes score over time and with treatment. RESULTS: In our prospective study for the assessment of trauma patients, mean changes in percentage scores were as expected large and all effect sizes were large (≥0.8). For elective patients, the mean improvement in scores and effect sizes were moderate. The Minimal Detectable Change (MDC95) ranged from 6 to 8 on the percent scores. The Minimal Important Difference (MID) for elective patients ranged from 7 to 17%. Half the standard deviation of baseline domain scores (often equated to MID) ranged from 11 to 18 on the percent scale. CONCLUSIONS: The results from the study demonstrated the longitudinal validity and responsiveness of the domain scales. The Questionnaire uniquely offers an expedient and budget conscious means to evaluate the effectiveness of the treatment of children’s foot or ankle problems from both the child and parent/caregivers perspective. The questionnaire has broad utility both in routine clinical settings, or applied research to evaluate treatment programmes and interventions used in paediatric orthopaedics, trauma and rheumatology.
