Abstract

We investigate several fragments of multiplicative linear logic, in a natural deduction setting and with the aim of a better understanding of the par connective. We study, first, a pre-tensorial calculus, which is strengthened then in the standard tensorial fragment. The addition of a further pre-tensorial connective yields (a natural deduction version of) Full Intuitionistic Linear Logic. A further strengthening of the rules leads to the full classical multiplicative logic. Some proof-theoretical properties of the systems are investigated.

1. Introduction

This study emerges as an attempt to better understand the “par” connective of linear logic, in its logical and computational content, from a computer science perspective. In the context of functional programming, the Curry–Howard isomorphism – relating natural deduction intuitionistic proofs and their normalization process to programs and their execution – is a leading idea. Proofs are effective transformations of several inputs (assumptions) into one output (conclusion), as it is apparent from the correspondence between implication and function space, and from the categorical interpretation of the intuitionistic natural deduction.

In this perspective there is no real problem with linear logic (e.g. [1, 4, 7]) but for par, which has not received any attention from a natural deduction (i.e. input–output) perspective. The reason seems to stay in the apparent impossibility to formulate a suitable introduction–elimination pair, when sticking to single conclusion systems. The problem obviously does not arise either in sequent calculus or in proof-nets, which...
are intrinsically multiconclusion calculi. Note, moreover, that even in an intuitionistic setting (traditionally single-conclusion), the Full Intuitionistic Linear Logic (FILL) of [3], which is an input–output interpretation, is formulated as a multiconclusion sequent calculus.

Semantically speaking, a par is a monoidal tensor. Thus, our strategy of investigation has been to isolate a simple ambience (the pure implicative fragment) and to enrich it stepwise, starting from the weakest possible connective (i.e. a covariant bifunctor; Section 2). The strengthening of this connective into an intuitionistic par allowed interesting reflections on the logical power of this “intuitionistic” system (Section 3). Indeed, from the simple formulation of the calculus and the logical equivalence with FILL, we see that this intuitionistic par is a restricted tensor (Section 3.2), leaving still open the problem of finding a convincing intuitionistic interpretation for par. It is not too surprising that in the classical case the par is amenable to a better treatment (Sections 4 and 5), resulting in a natural deduction system enjoying both proof-theoretically (explicit introduction–elimination rules for par) and computationally (normalization) good properties.

2. Pre-tensorial linear logic

All the systems we study in this paper are built on top of the implicational fragment of linear logic, formulated in natural deduction style according to the following definition.

**Definition 2.1.** The pure implicative natural deduction system of linear logic (N-ill) is given by the following axioms and rules:

\[
\begin{align*}
A & \\
\vdots & \\
\frac{A & \quad \vdash B \rightarrow A}{B \rightarrow A} \quad \text{\$} & \\
\frac{B \quad B \rightarrow A &}{A} \quad \rightarrow \&
\end{align*}
\]

Here, and in the following, \([B]\) means that exactly one occurrence of the formula \(B\) is discharged; as usual, other assumptions may be present. We write \(\Gamma \vdash A\), where \(\Gamma\) is a multiset of formulas, if there is a deduction of \(A\) whose open assumptions (each corresponding to a leaf) are exactly the formulas of \(\Gamma\).

Additional systems will be obtained adding to N-ill connectives and rules. We will use the notation \(\mathbb{LL}\text{-list-of-connectives}\text{-list-of-rules}\) to denote the natural linear deduction system obtained by adding to N-ill the new connectives in the “list-of-connectives” equipped with the rules in the “list-of-rules”.
We study, first, the simple system obtained by adding a binary connective \( \cdot \), with, as only rule, the following replacement rule (\( \cdot \mathcal{R} \)):

\[
\begin{array}{ccc}
[A] & [B] \\
\vdots & \vdots \\
A \cdot B & C & D \\
C \cdot D & \cdot \mathcal{R}
\end{array}
\]

\( A \cdot B \) is the "major premise" of the rule, while \( C \) and \( D \) are its "minor premises".

We call the resulting system, \( \mathcal{L} \cdot \mathcal{L} \), pre-tensorial linear logic (or \( \mathcal{P} \cdot \mathcal{L} \)). It is a very simple system, with good proof-theoretical properties (see Section 2.1), but very limited on the logical side. Indeed, from a categorical point of view, \( \cdot \) is simply a bi-functor, without any "intrinsic" property. In particular:

**Proposition 2.2.** The \( \cdot \) is not commutative and is not associative.

And, moreover, its rule is too weak to characterize completely the connective:

**Proposition 2.3.** Let \( \circ \) be another connective with the same rule of \( \cdot \). Then

\[
\mathcal{L} \cdot \mathcal{L} \vdash A \circ B \rightarrow A \cdot B.
\]

It is a situation common to all "intensional" connectives, like the modalities, when their proof theory is formulated in the standard way.

### 2.1. Reductions and properties

We may equip system \( \mathcal{P} \cdot \mathcal{L} \) with a reduction relation on proofs, adding to the usual \( \beta \) reductions for \( \rightarrow \) the following \( \cdot \) reduction:

\[
\begin{array}{ccc}
[A] & [B] \\
\vdots & \vdots \\
A \cdot B & C & D \\
C \cdot D & \vdots & \vdots \\
\end{array} \quad \begin{array}{ccc}
(C) & (D) \\
\vdots & \vdots \\
E & F \\
E \cdot F
\end{array} \quad \begin{array}{ccc}
A \cdot B & E & F \\
\vdots & \vdots \\
E \cdot F
\end{array}
\]

It is no surprise that under the reduction relation defined by this rule, \( \mathcal{P} \cdot \mathcal{L} \) enjoys good properties.

**Theorem 2.4.** \( \mathcal{P} \cdot \mathcal{L} \) is strongly normalizing.
Proof. Define the size \( s(\pi) \) of a deduction \( \pi \) whose last rule has premise \( \pi_1 \) (respectively, premises \( \pi_1, \pi_2, \pi_3 \)) as \( s(\pi_1) + 1 \) \((s(\pi_1) + s(\pi_2) + s(\pi_3) + 1) \). Due to the linearity of the calculus, the size of the deduction strictly decreases in any reduction step. 

In spite of the impurity of rule \( \bullet R \) (its premises behave as in an elimination rule, while its conclusion behaves as in an introduction rule), \( \text{PtLL} \) enjoys also the subformula principle. We are not interested in the study of the subformula principle "per se", but it is interesting in order to have a full understanding of the \( \bullet R \) rule.

The usual notion of track has to be extended, in order to handle the nonstandard behavior of rule \( \bullet R \).

Definition 2.5. A track of a derivation is a sequence of formulas \( A_0, \ldots, A_n \) such that

(i) \( A_0 \) is an assumption not discharged by an application of \( \bullet R \);

(ii) \( A_i \), for \( i < n \), is not the minor premise of \( \neg \varnothing \) and either

1. \( A_i \) is not the major premise of \( \bullet R \) and \( A_{i+1} \) is directly below \( A_i \) or
2. \( A_i \) is the major premise of \( \bullet R \) and \( A_{i+1} \) is an assumption discharged at that rule;

(iii) \( A_n \) is either the minor premise of a \( \neg \varnothing \), or the conclusion of the deduction.

In the following theorem, whose proof is routine [6], note the double role played by the \( \bullet R \) rule: its major premise belongs to the E-part, while its minor premises belong to the I-part (or is the minimum formula).

Theorem 2.6. Let \( D \) be a normal derivation and let \( \pi = A_0, \ldots, A_n \) be a track in \( D \). Then there is a formula \( A_i \) which separates two (possibly empty) parts of \( \pi \) (called the E-part and the I-part) such that:

(i) for each \( A_j \) of the E-part: \( j < i \), \( A_j \) is the major premise of an elimination rule or of \( \bullet R \), and \( A_{j+1} \) is a subformula of \( A_j \);

(ii) \( A_i \), for \( i \neq n \), is a premise of an introduction rule, or a minor premise of a \( \bullet R \) rule;

(iii) for each \( A_j \) of the I-part: \( i < j \), \( A_j \) is either a premise of an introduction rule, or a minor premise of a \( \bullet R \) rule, and \( A_j \) is a subformula of \( A_{j+1} \).

Proof. Suppose the thesis is false. Then the proof is not normal. Argue by cases. \( A_j \) cannot be the premise of an introduction rule and \( A_{j+1} \) the major premise of an elimination, for normality; \( A_j \) cannot be the premise of an introduction rule and \( A_{j+1} \) the major premise of \( \bullet R \), for the main connective of \( A_{j+1} \) is not \( \bullet \); \( A_j \) cannot be the minor premise of \( \bullet R \) and \( A_{j+1} \) the major premise of \( \bullet R \), for the main connective of \( A_{j+1} \) is not \( \neg \); \( A_j \) cannot be the minor premise of \( \bullet R \) and \( A_{j+1} \) the major premise of \( \bullet R \), for normality. 

Theorem 2.7. \( \text{LL} \) enjoys the subformula principle.
Proof. By induction on the order of a track (a track is of order 0 iff its last formula is the conclusion of the deduction, and is of order $p + 1$ if its conclusion is the minor premise of a $\neg \neg$ elimination), show that any formula appearing in a track is subformula of the conclusion or of one undischarged hypothesis. □

2.2. Toward tensorial linear logic

Theorem 2.6 suggests a way to strengthen $\text{PtLL}$, separating in two different rules the introduction and the elimination behavior of $\bullet \mathcal{R}$. Since a minor premise belongs to the $I$-part and is followed in a track by the conclusion of the rule, a suitable introduction rule is obtained simply, by taking as its premises the minor premises of $\bullet \mathcal{R}$ and as conclusion the conclusion of the $\bullet \mathcal{R}$, namely

\[
\begin{array}{c}
\vdots \\
C & D \\
\hline
C \cdot D & \bullet \mathcal{I}
\end{array}
\]

Analogously, since the major premise of $\bullet \mathcal{R}$ belongs to the $E$-part and is followed in a track by one of the discharged assumptions, we may obtain an elimination rule by taking as its major premise the major premise of $\bullet \mathcal{R}$, as discharged hypotheses the discharged hypotheses of $\bullet \mathcal{R}$, and as conclusion a "new" formula:

\[
\begin{array}{c}
\vdots \\
A \cdot B \\
\hline
C & \bullet \mathcal{E}
\end{array}
\]

Now, in these two rules we immediately recognize those for the linear connective $\otimes$. The logic $\text{LL}_{\otimes, \bullet \mathcal{R}}$ coincides therefore with the tensorial fragment of $\text{LL}$, without the constant $1$. We will then use $\otimes$ for the connective $\bullet$ equipped with these two rules. It is obvious that the rule $\bullet \mathcal{R}$ is derived in $\text{LL}_{\otimes, \bullet \mathcal{R}}$.

3. Linear intuitionism?

3.1. Good news

Having obtained the tensorial logic $\text{LL}_{\otimes, \bullet \mathcal{R}}$, we may now exploit the observation we made on the intensionality of a connective defined by the only rule $\bullet \mathcal{R}$ and look what happens to the tensorial logic based on $\otimes$ when we add a further (pre)tensor connective $\bullet$. We are thus interested in the system $\text{LL}_{\otimes, \bullet \mathcal{R}}$.

The two connectives interact in a nice form, since

$$\text{LL}_{\otimes, \bullet \mathcal{R}} \vdash B \otimes (A \bullet D) \rightarrow (B \otimes A) \bullet D.$$
This important weak distributivity property is at the heart of the interpretation of linear logic into categories. Cockett and Seely [2] show how it is necessary in order to model the cut rule in classical linear logic; DePaiva and Hyland [3] build over it an interesting system for an intuitionistic fragment of linear logic. Standard formulations of intuitionistic linear logic (e.g. [5]) stem from the usual syntactic restriction (at most one formula to the right) of the two-sided sequent formulation of the classical version. Since the right rule for par does not make sense under this restriction, par has been banned from the intuitionistic fragment. Starting from the semantic intuition of a category with two monoidal operations connected by weak distributivity, DePaiva and Hyland realized that an (intuitionistic) system with par was possible, in a multiconclusion setting and (for ensuring cut-elimination) with term annotations. They prove the calculus (FILL: Full Intuitionistic Linear Logic) complete with respect to full multiplicative categories (i.e. symmetric monoidal closed categories which are weakly distributive), which are the "natural" models of FILL.

What are, then, the relations between FILL and our $LL^{\otimes, \cdot, 1, \bot}$, with $\cdot$ playing the role of intuitionistic par? To answer the question, let us first add to our system rules for the constants $1$ and $\bot$, plus rules for commutativity and associativity of $\cdot$. As usual, we will write $A^+$ for $A \rightarrow \bot$. The simplest rules for the constants are the naive ones:

$$\frac{A}{A \cdot 1} \quad \frac{A \cdot \bot}{A}$$

Commutativity and associativity are simply obtained by

$$\frac{B \cdot C}{C \cdot B} \text{ comm}$$

$$\frac{A \cdot (B \cdot C)}{(A \cdot B) \cdot C} \quad \frac{(A \cdot B) \cdot C}{A \cdot (B \cdot C)}$$

Let $N$-FILL ($= LL^{\otimes, \cdot, 1, \bot}$) be the resulting system.

**Theorem 3.1.** $\Gamma \vdash A$ iff $\Gamma \vdash_{FILL} A$.

**Proof.** ($\Rightarrow$) Easy, since all the rules of $N$-FILL are clearly valid in FILL.

($\Leftarrow$) For a syntactic proof of this fact one needs first to decorate $N$-FILL proofs with terms and, then, to prove that each FILL term can be permuted in a suitable way.

---

2 Proof theoretical purist: wait...!
to obtain an $\text{N-FILL}$ term. The crucial point of this process is the treatment of the restriction on the right rule for $\circ$. This syntactic proof, however, is long and tedious. We sketch, instead, an economical semantical proof. Note, first, that $\text{N-FILL}$ contains all the ingredients to build a full multiplicative category, say $\text{NF}$. In order $\text{NF}$ to be such a category, of course, one needs to add suitable quotients of arrows, for unicity and coherence, but these will not identify objects. Since $\text{FILL}$ is complete for weakly distributive categories, any proof $\Gamma \vdash_{\text{FILL}} A$ corresponds to an arrow in $\text{NF}$, that is to a (quotient of proofs) $\Gamma \vdash_{\text{N-FILL}} A$. 

3.2. Bad news

Unfortunately, as far as provability is concerned, $\text{N-FILL}$ is not big improvement over pure tensorial logic. Define the following “collapsing” map $(\_)^*$:

\[(\bot)^* = 1,
(A \otimes B)^* = (A)^* \otimes (B)^*,
(A \otimes B)^* = (A)^* \otimes (B)^*,
(A \rightarrow B)^* = (A)^* \rightarrow (B)^*.
\]

**Theorem 3.2.** If $\pi$ is a proof of $\Gamma \vdash_{\text{N-FILL}} A$, then we can construct a proof $\pi^*$ of $(\Gamma)^* \vdash_{\text{N-FILL}} (A)^*$.

**Proof.** Easy induction on the length of $\pi$ and by cases on its last rule. The only “interesting” cases are those involving the $\otimes$ connective: we will show only the one in which the last rule is $\otimes$, as it shows how the bifunctorial rules must be replaced by a pair of $\otimes$, $\otimes$ rules:

\[
\begin{array}{cccc}
\Gamma & [A] & [B] & \Sigma \\
\vdots & \vdots & \vdots & \vdots \\
A \otimes B & C & D & \bullet
\end{array}
\]

By induction hypothesis and by using the $\otimes$, $\otimes$ rules we have Fig. 1.

The opposite implication obviously does not hold. For $F = ((A \otimes B) \rightarrow C) \rightarrow (A \rightarrow (B \rightarrow C))$, $\vdash (F)^*$, but it is easy to show, in view of the cut-elimination theorem for $\text{FILL}$, that $\vdash F$. The logical laws on $\rightarrow, \otimes, \bot$ are thus a subset (modulo renaming) of the laws on $\rightarrow, \otimes, 1$, a situation hardly satisfactory (Fig. 2). Consider, indeed, what happens for the (nonlinear) connectives “and”, “or”. When we go from their classical formulation to the intuitionistic one, we preserve a clean-cut separation between them – they still have a common set of logical laws, but none of them is a subset of the
other. In the linear case, instead, Theorem 3.2 tells us that the intuitionistic par is a restricted version of the tensor $\otimes$.

The moral we draw from this section is that, despite the deep semantical motivation and the proof-theoretical interest of a system like FILL (whose cut-elimination depends in an essential way from the term annotations), it is difficult to call intuitionistic a
connective that is only a restricted tensor. The only fact that in this fragment \( A \otimes A^\perp \) it is not provable, seems too limited a reason. Due to the intensionality of its par, its status is somehow similar to that of many temporal logics, where different logics are characterized by connectives with increasing power.

4. Toward classical linear logic

If the natural deduction formulation shows that intuitionistic par is debatable, can we gain something passing to classical par? Let us look at ways to extend the pre-tensorial rule

\[
\begin{array}{c@{\hspace{1cm}}ccc@{\hspace{1cm}}c}
\hline
& [A] & [B] & \vdots & \vdots \\
\hline
& A \otimes B & C & D & \phi \mathcal{R} \\
C & \phi D & \hline
\end{array}
\]

in order to have a classical \( \phi \). Since in MLL one can prove \( A \otimes A^\perp \) (where, with a little abuse of language, in the case of \( A = 1, A^\perp \) may denote not only \( 1 \rightarrow \perp \), but also \( \perp \)), let us start adding to \( \text{LL}^{\phi, \otimes, 1} \) the axiom

\[
\frac{A \otimes A^\perp}{\phi \text{-ax}}
\]

From this and rule \( \phi \mathcal{R} \), we obtain Fig. 3, which can be formulated as introduction rule:

\[
\begin{array}{c@{\hspace{1cm}}ccc@{\hspace{1cm}}c}
\hline
& [A] & [A^\perp] & \vdots & \vdots \\
\hline
& C & D & \phi \mathcal{R} \\
\hline
\end{array}
\]

This (and its symmetric) is the “official” introduction rule for \( \phi \), which trivially allows the proof of \( A \otimes A^\perp \).

\[
\begin{array}{c@{\hspace{1cm}}ccc@{\hspace{1cm}}c}
\hline
& [A] & [A^\perp] & \vdots & \vdots \\
\hline
& A \otimes A^\perp & \phi \text{-ax} & C & D \\
C & \phi D & \phi \mathcal{R} \\
\hline
\end{array}
\]

Fig. 3.
Let us start again this euristic game. In MLL, $\bot$ is the identity of $\emptyset$. In particular, we need a way of obtaining a proof of $B$, given a proof of $B \emptyset \bot$. Assume then given the rule

$$
\begin{array}{c}
[A] \\
\vdots \\
A \emptyset B \quad \bot \\
\bot \emptyset B \\
\hline
\bot \\
\end{array}
$$

and combine it with $\emptyset \emptyset$ to form Fig. 4. Once again, this inference can be formulated as an elimination rule:

$$
\begin{array}{c}
[A] \\
\vdots \\
A \emptyset B \quad \bot \\
\bot \emptyset \emptyset \\
\hline
\emptyset \emptyset \\
\end{array}
$$

This (and its symmetric) is the "official" elimination rule for $\emptyset$. Observe it is not independent of the others connectives: its premises contain, besides $\emptyset$, also $\bot$.

5. Classical MLL

After the discussion of the last section, let N-ml be the system obtained by adding to LL the following rules:

- Introduction rules:

\[
\begin{array}{cccc}
[A] & [A^\top] \\
\vdots & \vdots \\
C & D \\
\hline
C \emptyset D & \emptyset \emptyset^1 \\
\end{array}
\quad
\begin{array}{cccc}
[A^\top] & [A] \\
\vdots & \vdots \\
C & D \\
\hline
C \emptyset D & \emptyset \emptyset^2 \\
\end{array}
\]

where in the case of $A = 1$, $A^\top$ may be either $1 \rightarrow \bot$ or $\bot$.

\[\text{The reverse deduction is easily proved by}
\begin{array}{c}
[1] \\
B \\
\hline
B \emptyset \bot \\
\end{array}
\quad
\begin{array}{c}
\bot \\
\hline
\emptyset \emptyset \\
\end{array}
\]
• Elimination rules:

\[
\begin{array}{c}
\vdash A \Rightarrow B \\
\vdash B \Rightarrow C
\end{array}
\]

\[
\frac{A \Rightarrow B}{B} \quad \frac{B \Rightarrow A}{B}
\]

Proposition 5.1. The $\varnothing \mathcal{A}$ pre-tensorial rule is derivable in $\mathsf{N-mll}$.

Proof. See Fig. 5. $\square$

The following proposition shows how the splitting of the pre-tensorial rule allows to recover commutativity and associativity.

Proposition 5.2. The $\varnothing$ connective of $\mathsf{N-mll}$ is commutative and associative.

Proof. See Fig. 6. $\square$

Theorem 5.3

\[
\Gamma \vdash_{\mathsf{N-mll}} A \iff \Gamma \vdash_{\mathsf{MLL}} A.
\]

Proof. ($\Rightarrow$) All the $\mathsf{N-MLL}$ rules are sound in $\mathsf{MLL}$.

\[
\begin{array}{c}
\vdash A \\
\vdash C
\end{array}
\]

\[
\frac{A \Rightarrow B}{B} \quad \frac{B \Rightarrow A}{B}
\]

\[
\frac{\vdash C}{C \Rightarrow D} \quad \frac{\vdash D}{\vdash \mathcal{J}}
\]

Fig. 5.

\[
\frac{\vdash A \Rightarrow \mathcal{J}}{\vdash A \Rightarrow (B \Rightarrow C)} \quad \frac{\vdash B \Rightarrow C}{\vdash A \Rightarrow (B \Rightarrow C)}
\]

\[
\frac{\vdash A \Rightarrow B}{B \Rightarrow C} \quad \frac{\vdash B \Rightarrow A}{B \Rightarrow C}
\]

\[
\frac{\vdash [A] \quad [A^\perp]}{\vdash [C] \quad [C^\perp]} \quad \frac{\vdash [C] \quad [C^\perp]}{\vdash (A \Rightarrow B) \Rightarrow C}
\]

Fig. 6.
From Theorem 3.1 and the discussion of the previous section, if $\Gamma \vdash_{\text{FILL}} A$, then $\Gamma \vdash_{N\text-mll}} A$. On the other hand, it is an easy exercise to show that $\text{FILL} + A \varphi A \perp = \text{MLL}$. Since $\vdash_{N\text-mll}} A \varphi A \perp$, we conclude. □

5.1. On the $\varphi$ introduction rule

One of the novelties of our approach is the $\varphi$ introduction rule which, in the discharging of a “negated” formula, bears similarities with reductio ad absurdum rule (RAA) of classical logic. It is easy to see how RAA is “implemented” in $\text{N-mll}$:

\[
\begin{array}{c}
[A] \\
\vdots \\
\lnot A \perp \\
\lnot \varphi A \\
\hline
A
\end{array}
\]

Note RAA is obtained with a restricted instance of $\varphi.\mathcal{F}$, where the “non negated” discharged formula is an assumption. In fact, such a restriction preserves the logical power of $\text{N-mll}$.

**Proposition 5.4.** There is an effective transformation of a $\text{N-mll}$ proof $\pi$ in another $\text{N-mll}$ proof $\pi'$, s.t. in $\pi'$ each occurrence of the rule $\varphi.\mathcal{F}$ is bound to the following “formats”:

\[
\begin{array}{c}
[A] \\
\vdots \\
[A] \\
\hline
A \varphi B \\
B [A] \\
\hline
A \varphi B
\end{array}
\]

**Proof (sketch).** Replace each occurrence

\[
\begin{array}{c}
[A] \\
\vdots \\
C \\
\hline
C \varphi D
\end{array}
\]

of $\varphi.\mathcal{F}$ in $\pi$, with Fig. 7. □

Hence, from the point of view of the pure provability power, the $\varphi.\mathcal{F}$ rules may be replaced with the new rules

\[
\begin{array}{c}
[A] \\
\vdots \\
R \\
\hline
A \varphi B \\
R \\
\hline
B \varphi A
\end{array}
\]

which correspond to the definition of $\rightarrow$ in terms of $\varphi$. 
6. Reductions

Before defining the N-mlI reduction, we introduce a new proof figure that we call "absorption" (Fig. 8). Such a figure cannot be reduced in N-mlI. This is consistent with the linearity of the calculus, in particular with the constraint that all the open hypotheses of a deduction be "concrete" leaves of the proof tree. This form of implicit weakening (the other undischarged assumptions of the deduction of $\perp$ from $A^\perp$ are present, though not necessary for the derivation of $C$) is coessential to a formalization of linear proofs as proof trees.

We will write an absorption as

$$
\begin{array}{c}
[A^\perp] \\
\vdots \\
D \\
[A] \\
\perp \\
\hline \\
A \phi \perp \\
\vdots \\
C \\
\hline \\
C \phi D
\end{array}
$$

Fig. 7.

**Remark.** We have in fact four absorption figures, one for each combination of $\phi \otimes'\!$, $\phi A$ with $\phi \otimes'\!$, $\phi A$.

6.1. $\beta$ Reductions

We have the usual $\beta$ redexes originated by $\rightarrow, \otimes, \mathbf{1}$ plus the new $\phi$ redexes.

A $\phi$ redex is a sequence $\phi \otimes - \phi \otimes$ that does not belong to an absorption figure. We have four kind of redexes, one for each combination of $\phi \otimes^1, \phi \otimes^2$ with $\phi \otimes^1, \phi \otimes^2$; we will give a specific case, the other are analogous (see Fig. 9). $B \phi C$ is the principal formula of the redex.

6.2. Commutative reductions

The usual commutative contractions for $\otimes$ and $\mathbf{1}$, formed by a $\otimes \phi$ ($\mathbf{1} \phi$) followed by an elimination rule.
6.3. Normalization

Let us denote with $\rightarrow$ the compatible closure of $\rightarrow$, and with $\rightarrow\rightarrow$ the transitive and reflexive closure of $\rightarrow$. The "degree" of a redex is the usual structural complexity of its principal formula. It is immediate to prove that:

**Proposition 6.1.** The contractions previously defined are correct in $N$-$\text{mll}$. 

Now we can formulate the normalization theorem:

**Theorem 6.2.** The reduction relation $\rightarrow\rightarrow$ is normalizing.

**Proof.** Completely standard (see [8]). We outline here the main idea. Define the degree, $d(\mathcal{D})$, of a deduction $\mathcal{D}$ as the maximum of the degrees of the redexes in $\mathcal{D}$. Set now $\mu(\mathcal{D}) = (d(\mathcal{D}), m)$, where $m$ is the sum of the lengths of redexes of degree $d(\mathcal{D})$. By induction on $\mu(\mathcal{D})$ (under the lexicographic ordering) we prove that, selected a redex of maximal degree in $\mathcal{D}$, we can reduce $\mu(\mathcal{D})$. 

7. Conclusions

We have proposed some new natural deduction systems for various versions of the par connective. These systems show that, contrary to most folklore, the classical natural deduction methods can indeed cope with par.

Besides this genuine proof-theoretical interest, we are convinced that a deeper insight into a system can be gained only by looking at it from many different perspectives, each revealing properties that others hide. A good example of this situation is the
relation between optimal lambda-reduction and linear logic, which becomes apparent only in the proof-net formulation and can be only reconstructed *a posteriori* in the sequent calculus approach.

Without being too optimistic, we believe the proposed systems may point out new computational interpretation, with a particular emphasis on concurrency. The shape of the classical introduction rule, in fact, may be seen as the definition of a concurrent composition operator with a synchronous communication (represented by the simultaneous discharging of the two dual premises).
