The purpose of this study is to investigate the advantage of DES for FP lesions in diabetic patients.

**METHODS** This is a single center, retrospective study. Between July 2008 and April 2013, 74 lesions in 58 diabetic patients were treated with bare metal stents (BMS group). 52 lesions in 42 diabetic patients were treated with Zilver PTX paclitaxel-eluting nitinol stents (DES group). We evaluate the clinical outcomes as primary patency, freedom from re-occlusion, major adverse limb events (MALE) and all-cause death after endovascular therapy. Stent patency was assessed by either duplex ultrasound or angiography.

**RESULTS** Mean follow-up period were 616±346 days in BMS group and 372±141 days in DES group. Primary patency at a year was 82% and 87%. (p=0.96) Freedom from re-occlusion at a year were 92% and 91%. (p=0.26) Freedom from MALE was 94% and 91%. (p=0.45) Survival rate were 86% and 95%. (p=0.18) Multivariate logistic regression analysis revealed TASC II class C/D increased the risk of restenosis/reocclusion with an odds ratio [95% confidence interval] of 3.34 [1.30 to 9.03] (p=0.01).

**CONCLUSION** Femoropopliteal stenting for diabetic patients with drug-eluting stent offers no significant advantage over bare metal stent in middle-term clinical outcome.

**Success Rate of Endovascular Recanalization in Iliac and Femoral Chronic Total Occlusion and Alternative Treatment Options After Reentry Failure**

KangWoong Jun,1 Jang Yong Kim2

1School of Medicine The Catholic University of Korea, Korea (Republic of); 2Seoul St. Mary’s Hospital, Korea (Republic of)

**BACKGROUND** The reentry failure is one of major causes influencing the technical success of endovascular treatment of CTOs in iliac and femoral arteries. This study was conducted to evaluate the success rate of reentry during endovascular recanalization of iliac and femoral CTOs and review the alternative treatment after reentry failure in our institute.

**METHODS** This is a retrospective study from prospectively registered database of patients underwent endovascular treatment for long iliac artery and femoral artery CTO from October 2008 to September 2014 in Seoul St. Mary hospital and Inha university hospital. The patients treated with acute thrombotic occlusion and hybrid technique were excluded. We analyzed the baseline characteristics of patients, success rate of reentry, and alternative options after reentry failure. Initial success rate was defined as a success of recanalization with initial strategy, overall success rate as total success of recanalization with initial vascular access and/or alternative endovascular treatment (e.g. using CTO device such as Outback™, Truepath™, Offroad™ etc., or distal vessel puncture (Rendezvous or SAFARI technique) after failure of initial attempt.

**RESULTS** Fifty seven iliac CTOs (49 patients) and 19 femoral CTOs (18 patients) were enrolled. Initial success rate was 48 (84.2%) and 11 (57.9%) (p=0.026), and overall success of recanalization was 50 (87.7%) in iliac CTO group and 16 (84.2%) in femoral CTO group (p=.704). The lesions which had angiographic stump, the initial success rate was 39 (90.9%), and the lesions those without stump, the initial success rate was 64.3% in iliac CTOs (p=.003), and in femoral CTOs were 71.4 vs. 20% (p=.111), respectively.

**CONCLUSION** In this study the initial success rate was much higher in iliac CTOs (84.2%) than in femoral CTOs (57.9%) which was
statistically significant (p < 0.05). However, overall success rate has increased to 87.7% in iliac CTO group and to 84.2% in femoral CTO group. His alternative strategies after the initial reentry failure is very important and can improve overall success rate of endovascular recanalization of the iliac and femoral CTOs.

1 Year Clinical Outcome of Endovascular Therapy for the Critical Limb Ischemia with Below the Knee Disease

Yasuhiro Kaetsu

Kakogawa East City Hospital, Japan

**BACKGROUND** Endovascular therapy (EVT) have been developed, however patients with critical limb ischemia (CLI) have a poor prognosis. To evaluate 1 year clinical outcomes after EVT for CLI with below-the-knee (BK) disease from daily practice.

**METHODS** Between 2011 July and 2013 July, 40 patients with CLI were treated BK interventions. We investigated the occurrence of clinical events within 12 months after EVT, such as death, major and minor amputation, and revascularization.

**RESULTS** Of these patients, mean age was 75.0±8.2 years, 52.5% (21/40) was male. Rutherford class 4 was 8 patients, 5 was 30 patients and 6 was 2 patients. Hypertensive patients were 33 (82.5%), Dyslipidemia were 31 (77.5%), Diabetes were 25 (62.5%), prior and current smoker were 19 (47.5%) and Hemodialysis patients were 9 (22.5%). 12 months after EVT (follow up % was 95%), there were 2 deaths (8.3%), 0 major amputation (0%), 6 minor amputations (25.0%). 33.3% of all patients were needed revascularizations.

**CONCLUSION** 1 year clinical outcomes after endovascular therapy for critical limb ischemia with below-the knee disease were acceptable in our hospital.

Mu-Yang Hisieh,1 Chih-Cheng Wu1

1National Taiwan University Hospital, Hsin-chu Branch, Taiwan

**BACKGROUND** Acute mesenteric ischemia carries high morbidity and mortality rates unless urgently treated. In patients without evident bowel necrosis on computer tomography, the treatment remained controversial since an experienced hospital. When a suspicious case progressed into septic shock, the patient was usually too ill to receive definitive surgical management. Unless an early invasive angiography strategy was adopted, it is sometimes difficult to establish definitive diagnosis in early cases without signs of bowel necrosis. Hence, we developed a protocol-driven strategy to improve definitive diagnosis, endovascular salvage, and survival rates. We aim to report our two-year results with this protocol-driven strategy.

**METHODS** We developed a protocol for patients with clinically suspected acute mesenteric ischemia visiting the emergency room in a rural hospital. Patients who presented with acute abdominal pain with suspicious mesenteric ischemia by contrast CT study were enrolled and prospectively followed. The inclusion criteria were: 1. emergency room visit for acute abdominal pain or shock with elevated lactate level, 2. suspected thrombus formation or decreased flow in one of the mesenteric vessels. The exclusion criteria were: 1. definitive pathology other than ischemia found by CT and 2. Bowel necrosis mandating surgical exploration. A dedicated gastroenterologist, an interventional radiologist, two interventional cardiologists, and two general surgeons were invited to provide clinical judgment whether early invasive strategy is justified when no bowel necrosis signs were found by CT. We prospectively collected angiography findings, treatment results, complications, and survival rates of confirmed acute mesenteric ischemia. The primary outcome was survival in contrast CT cases.

**RESULTS** From August, 2012 to August, 2014, total 1916 contrast-enhanced abdominal computer tomography was performed in our emergency room for acute abdominal pain. Eight patients fulfilled the inclusion criteria. All enrolled patients proceed to complete the protocol of early invasive strategy. All had acute mesenteric ischemia confirmed by selective angiography. Endovascular salvage with equipment used in primary percutaneous coronary intervention for ST-elevation myocardial infarction was attempted. The angiographic success rate was 100% in non-calcified cases (6/8), but 0% in heavily calcified and high thrombus burden cases (2/8). The 30-day survival rate was 100% in angiographic success patients and 0% in failed cases. No procedure-related complication was noted. Five survived patients were discharged within very short ICU stay (less than 48 hours) and appeared well up to 90-day follow-up.

**CONCLUSION** In patients with suspected acute mesenteric ischemia, a protocol-driven approach with early invasive strategy improved patient outcome with acceptable safety and feasibility.

Randomized Comparison of Vascular Healing Response Between Self-Expanding Nitinol Stent and Self-Expanding Paclitaxel-Eluting Stent in the Superficial Femoral Artery: An Optical Frequency Domain Imaging Study

Kojiro Miki,1 Kenichi Fujiij,2 Masashi Fukunaga,3 Masaharu Ishihara2

1Hyogo College of Medicine, Japan; 2National Cerebral and Cardiovascular Center, Japan

**BACKGROUND** Similar to the coronary artery, late stent thrombosis (ST) due to delayed vascular healing is concerned after drug-eluting stent (DES) implantation in the superficial femoral artery (SFA). Therefore, we analyzed vascular response after DES implantation in the SFA with optical frequency domain imaging (OFDI).

**METHODS** Consecutive 34 de novo SFA lesions from 30 patients underwent endovascular therapy (EVT) were randomly assigned 1:1 to receive self-expanding bare-metal nitinol stent (BMS, 17 lesions) or self-expanding paclitaxel-eluting nitinol stent (PES, 17 lesions) implantation. Six months after initial EVT, follow-up angiography and OFDI examination were conducted to evaluate the vascular response to the stents. OFDI analyses were performed at 5-mm axial intervals throughout entire stented segments. Neointimal tissue (NIT) thickness inside all stent struts was measured. In the morphological OFDI analysis, the presence of thrombus, microvessels, peri-strut low intensity area (PLIA), and the optical appearance of NIT were analyzed. The optical appearance of NIT was classified into 3 patterns: homogeneous, layered, and heterogeneous patterns. The primary end-point was the percentage of uncovered stent strut at 6-month follow-up.

**RESULTS** The mean lesion length was 79 ± 46 mm. During follow-up period, 3 patients died, 2 patients refused follow-up examination, and 2 lesions were performed revascularization for restenoses of target lesions. Finally, follow-up angiography and OFDI were performed in 27 lesions and 12547 stent struts were analyzed. The binary angiographic restenosis rate at 6-month follow-up was 21.4% in BMS group and 7.7% in PES group (p = 0.01). The percentage of uncovered strut was higher in PES group compared to BMS group (55.2% vs. 2.6%, p < 0.01). Mean NIT thickness was smaller in PES group (426 ± 144 µm vs. 650 ± 165 µm, p < 0.01). Prevalence of thrombus, microvessels, and PLIA were similar between two groups. Also, there was no significant difference in the optical appearance of NIT.

**CONCLUSION** OFDI revealed that vascular healing after DES implantation in the SFA was impaired at chronic phase. An adjunctive therapy might be required for prevention of ST after DES implantation.

The Performance of an Exoseal Vascular Closure Device for Achievement of Hemostasis After Femoral Artery Access Cardiovascular Interventions

Masahiko Fujihara1

1Kishiwada Tokushukai Hospital, Japan

**BACKGROUND** Cardio vascular interventional procedures are still often performed through femoral artery access. Manual compression to the femoral artery is a traditionally method of hemostasis after procedure, but its long time to ambulation and inadequate hemostasis often occurred the complications included major hematomata, bleeding, arteriovenous fistula and deep venous thrombosis. Vascular closure devices (VCDs) are increasing used after various types of cardiovascular procedures including coronary, cerebrovascular and peripheral arterial intervention. And several types of VCDs have become available to the management of access site after those procedures. EXOSEAL VCD device is a bioabsorbable device designed for the sealing of femoral artery puncture site and has a visually guided closure function. EXOSEAL VCD device is a bioabsorbable device designed for achievement of the sealing of femoral artery puncture site and has a visually guided closure function.
